Lorentzian Kleinian groups

Charles Frances

Abstract. In this article we introduce some basic tools for the study of Lorentzian Kleinian groups. These groups are discrete subgroups of the Lorentzian Möbius group $O(2, n)$, acting properly discontinuously on some nonempty open subset of Einstein’s universe, the Lorentzian analogue of the conformal sphere.

Keywords. Lorentzian conformal geometry, Einstein’s universe, conformal dynamics, Kleinian groups.

1. Introduction

To understand a hyperbolic manifold $\mathbb{H}^{n+1}/\Gamma$ ($\mathbb{H}^{n+1}$ denotes here the $(n + 1)$-hyperbolic space and $\Gamma \subset O(1, n + 1)$ is a discrete group of hyperbolic isometries), a nice and powerful tool is the dynamical study of the conformal action of $\Gamma$ on the sphere $\mathbb{S}^n$. This deep relationship between hyperbolic and conformally flat geometry has a counterpart in Lorentzian geometry, often quoted by physicists as AdS/CFT correspondence. Let us first recall what is the Lorentzian analogue of the pair ($\mathbb{H}^{n+1}, \mathbb{S}^n$). The $(n + 1)$-dimensional Lorentzian model space of constant curvature $-1$ is called anti-de Sitter space, denoted $\text{AdS}_{n+1}$ (precisely, we are speaking here of the quotient of the simply connected model $\tilde{\text{AdS}}_{n+1}$ by the center of its isometry group, see [O’N], [Wo]). This space, like the hyperbolic space, has a conformal boundary. It is called Einstein’s universe, denoted $\text{Ein}_n$, and it can be defined, up to a two-sheeted covering, as the product $\mathbb{S}^1 \times \mathbb{S}^{n-1}$ endowed with the conformal class of the metric $-dt^2 \times g_{\mathbb{S}^{n-1}}$. From the conformal viewpoint, Einstein’s universe has a lot of properties reminiscent of those of the sphere. In particular, the group $O(2, n)$ of isometries of $\text{AdS}_{n+1}$ turns out to be also the group of conformal transformations of $\text{Ein}_n$. The understanding of an anti-de Sitter manifold $\text{AdS}_{n+1}/\Gamma$ thanks to the conformal dynamics of $\Gamma$ on $\text{Ein}_n$ is one of the motivations for studying Lorentzian Kleinian groups, which we define by analogy with the classical theory as discrete subgroups of $O(2, n)$ acting freely and properly discontinuously on some nonempty open subset of $\text{Ein}_n$. 
Since the works of Poincaré and Klein at the end of the nineteenth century, the classical theory of Kleinian groups has generated a great amount of works and progressed very far (we refer the reader to [A], [Ka], [Ma], [MK] for a historical account and good expositions on the subject).

Other notions of Kleinian groups also appeared in other geometric contexts, such as complex hyperbolic and projective geometry (see for example [Go], [SV]).

To our knowledge, nothing systematic has been done for studying Lorentzian Kleinian groups, so that the aim of this article is to lay some basis for the theory. In particular, our first task is to build and study nontrivial examples of such groups.

The first part of the paper (Sections 3 and 4) is devoted to what could be called Lorentzian Möbius dynamics, namely the dynamical study of divergent sequences of $O(2, n)$ acting on $E_{1n}$. This dynamics appears richer than that of classical Möbius transformations on the sphere. This is essentially due to the fact that $O(2, n)$ has rank two, and the different ways to reach infinity in $O(2, n)$ induce different dynamical patterns for the action on $E_{1n}$. These patterns, which are essentially three, are described in Section 3, Propositions 3, 4 and 5. Let us mention here two new phenomena (with respect to the Riemannian context) illustrating the dynamical complications we are confronted with. Firstly, the Lorentzian Möbius group $O(2, n)$ is not a convergence group for its action on $E_{1n}$ (roughly speaking, a group $G$ acting by homeomorphisms on a manifold $X$ is a convergence group if any sequence $(g_i)$ of $G$ tending to infinity admits a subsequence with a “north–south” dynamics, i.e. a dynamics with an attracting pole $p^+$ and a repelling one $p^-$. See for example [A], p. 40, for a precise definition). Secondly, a discrete subgroup $\Gamma \subset O(2, n)$ does not always act properly on $\text{AdS}_{n+1}$.

In spite of these differences with respect to the classical theory it is still possible to define the limit set of a discrete subgroup $\Gamma \subset O(2, n)$ (see Section 4). This is a closed $\Gamma$-invariant subset $\Lambda_\Gamma \subset E_{1n}$, such that the action on the complement $\Omega_\Gamma$ is proper. Moreover it is a union of lightlike geodesics, so that it defines naturally a $\Gamma$-invariant closed subset $\hat{\Lambda}_\Gamma$ of $\mathbb{L}_n$, the space of lightlike geodesics of $E_{1n}$ (this space is described in Section 2.5). Unfortunately, the nice properties of the limit set in the classical case of groups of conformal transformations of the sphere are generally no longer satisfied in our situation. For example, the limit set that we define is not, in general, a minimal set for the action of $\Gamma$ on $E_{1n}$ (although $\hat{\Lambda}_\Gamma$ is sometimes minimal for the action of $\Gamma$ on $\mathbb{L}_n$, see Theorem 1 below). The groups $\Gamma \subset O(2, n)$ acting properly on $\text{AdS}_{n+1}$ are those whose behaviour is closest to that of classical Kleinian groups. They will be called groups of the first type. For them we get nice properties for the limit set.

**Theorem 1.** Let $\Gamma$ be a Kleinian group of the first type and $\Lambda_\Gamma$ its limit set.

(i) The action of $\Gamma$ is proper on $\Omega_\Gamma \cup \text{AdS}_{n+1} \subset E_{1n+1}$.
(ii) \( \Omega_\Gamma \) is the unique maximal element among the open sets \( \Omega \subset \text{Ein}_n \) such that \( \Gamma \) acts properly on \( \Omega \cup \text{AdS}_{n+1} \).

(iii) If moreover \( \Gamma \) is Zariski dense in \( O(2,n) \), then \( \Omega_\Gamma \) is the unique maximal open subset of \( \text{Ein}_n \) on which \( \Gamma \) acts properly, and \( \Lambda_\Gamma \) is a minimal set for the action of \( \Gamma \) on \( \mathbb{L}_n \).

In Section 5, we give several examples of families of Lorentzian Kleinian groups. These basic examples being constructed, it is natural to try to combine two of them to get other more complicated examples. This is the aim of Section 6, where we prove the following result (an analogue of the celebrated Klein’s combination theorem):

**Theorem 2.** Let \( \Gamma_1 \) and \( \Gamma_2 \) be two cocompact Lorentzian Kleinian groups with fundamental domains \( D_1 \) and \( D_2 \). Suppose that both \( D_1 \) and \( D_2 \) contain a lightlike geodesic. Then one can construct from \( \Gamma_1 \) and \( \Gamma_2 \) another cocompact Kleinian group, isomorphic to the free product \( \Gamma_1 \ast \Gamma_2 \).

By a cocompact Kleinian group we mean a group acting properly on some open subset of \( \text{Ein}_n \) with compact quotient.

We then use Theorem 2 in Section 7 to construct Lorentzian Schottky groups. The study of such groups can be carried out quite completely. The limit set \( \Lambda_\Gamma \) and the topology of the conformally flat Lorentz manifold obtained as the quotient \( \Omega_\Gamma / \Gamma \) of the domain of properness are made explicit in this case, and we get:

**Theorem 3.** Let \( \Gamma = \langle s_1, \ldots, s_g \rangle \) \( (g \geq 2) \) be a Lorentzian Schottky group.

(i) The group \( \Gamma \) is of the first type.

(ii) The limit set \( \Lambda_\Gamma \) is a lamination by lightlike geodesics. Topologically, it is a product of \( \mathbb{R}P^1 \) with a Cantor set.

(iii) The action of \( \Gamma \) is minimal on the set of lightlike geodesics of \( \Lambda_\Gamma \).

(iv) The quotient manifold \( \Omega_\Gamma / \Gamma \) is diffeomorphic to the product

\[
\mathbb{S}^1 \times \left( \mathbb{S}^1 \times \mathbb{S}^{n-1} \right)^{(g-1)\sharp},
\]

where \( \left( \mathbb{S}^1 \times \mathbb{S}^{n-1} \right)^{(g-1)\sharp} \) is the connected sum of \( (g-1) \) copies of \( \mathbb{S}^1 \times \mathbb{S}^{n-1} \).

2. Geometry of Einstein’s universe

A detailed description of the geometry of Einstein’s universe can be found in [Fr1], [Fr2] and [CK]. Also, for the readers who are not very familiar with Lorentzian space-times of constant curvatures, good expositions can be found in [Wo], chapter 11, and [O’N], chapter 8. In this section we briefly recall (without any proof) the main properties which will be useful in this article.
2.1. Projective model for Einstein’s universe. Let \( \mathbb{R}^{2,n} \) be the space \( \mathbb{R}^{n+2} \), endowed with the quadratic form \( q^{2,n}(x) = -x_1^2 - x_2^2 + x_3^2 + \cdots + x_{n+2}^2 \). The isotropic cone of \( q^{2,n} \) is the subset of \( \mathbb{R}^{2,n} \) on which \( q^{2,n} \) vanishes. We call \( C^{2,n} \) this isotropic cone, with the origin removed. Throughout this article we will denote by \( \pi \) the projection from \( \mathbb{R}^{2,n} \) minus the origin on \( \mathbb{R}P^{n+1} \). The set \( \pi(\mathcal{C}^{2,n}) \) is a smooth hypersurface \( \Sigma \) of \( \mathbb{R}P^{n+1} \). This hypersurface turns out to be endowed with a natural Lorentzian conformal structure. Indeed, for any \( x \in C^{2,n} \), the restriction of \( q^{2,n} \) to the tangent space \( T_xC^{2,n} \), that we call \( \hat{q}^{2,n}_x \), is degenerate. Its kernel is just the kernel of the tangent map \( d_x \pi \). Thus, pushing \( \hat{q}^{2,n}_x \) by \( d_x \pi \), we get a well-defined Lorentzian metric on \( T\pi(x)\Sigma \). If \( \pi(x) = \pi(y) \) the two Lorentzian metrics on \( T\pi(x)\Sigma \) obtained by pushing \( \hat{q}^{2,n}_x \) and \( \hat{q}^{2,n}_y \) are in the same conformal class. Thus the form \( q^{2,n} \) determines a well-defined conformal class of Lorentzian metrics on \( \Sigma \). One calls Einstein’s universe the hypersurface \( \Sigma \) together with this canonical conformal structure.

The intersection of \( C^{2,n} \) with the Euclidean sphere defined by \( x_1^2 + x_2^2 + \cdots + x_{n+2}^2 = 1 \) is a smooth hypersurface \( \hat{\Sigma} \subset \mathbb{R}^{2,n} \). One can check that \( q^{2,n} \) has Lorentzian signature when restricted to \( \hat{\Sigma} \), and in fact, \( (\hat{\Sigma}, q^{2,n}|_{\hat{\Sigma}}) \) is isometric to the product \( (\mathbb{S}^1 \times \mathbb{S}^{n-1}, -dt^2 + g_{\mathbb{S}^{n-1}}) \). Now Einstein’s universe is conformally equivalent to the quotient of \( (\mathbb{S}^1 \times \mathbb{S}^{n-1}, -dt^2 + g_{\mathbb{S}^{n-1}}) \) by an involution (induced by the map \( x \mapsto -x \) of \( \mathbb{R}^{2,n} \)).

2.2. Conformal group. In the previous projective model for Einstein’s universe the subgroup \( \text{O}(2, n) \subset \text{GL}_{n+2}(\mathbb{R}) \) preserving \( q^{2,n} \) acts conformally on \( \text{Ein}_n \). In fact, the conformal group \( \text{Conf}(\text{Ein}_n) \) of \( \text{Ein}_n \) is exactly \( \text{PO}(2, n) \). Let us now recall the following result, which is an extension to Einstein’s universe of a classical theorem of Liouville in Euclidean conformal geometry (see for example [CK], [Fr3]):

**Theorem 4.** Any conformal transformation between two open sets of \( \text{Ein}_n \) is the restriction of a unique element of \( \text{PO}(2, n) \).

2.3. Lightlike geodesics and lightcones. It is a remarkable fact of pseudo-Riemannian geometry that all the metrics of a given conformal class have the same lightlike geodesics (as sets, but not as parametrized curves). In the case of Einstein’s universe, the lightlike geodesics are the projections on \( \text{Ein}_n \) of 2-planes \( P \subset \mathbb{R}^{2,n} \) such that \( q^{2,n}|_P = 0 \). Hence lightlike geodesics of \( \text{Ein}_n \) are copies of \( \mathbb{R}P^1 \).

Given a point \( p \) in \( \text{Ein}_n \), the **lightcone with vertex** \( p \), denoted by \( C(p) \), is the set of lightlike geodesics containing \( p \). In the projective model, if \( p = \pi(u) \), with \( u \) some isotropic vector of \( \mathbb{R}^{2,n} \), then \( C(p) \) is just \( \pi(P \cap C^{2,n}) \), where \( P \) is the degenerate hyperplane \( P = u^\perp \) (the orthogonal is taken for the form \( q^{2,n} \)). The lightcones are not smooth submanifolds of \( \text{Ein}_n \). The only singular point of \( C(p) \) is \( p \), and \( C(p) \setminus \{p\} \) is topologically \( \mathbb{R} \times \mathbb{S}^{n-2} \).
2.4. Homogeneous open subsets. We will deal in this paper with several interesting open subsets of $\text{Ein}_n$, all obtained by removing from $\text{Ein}_n$ the projectivization of peculiar linear subspaces of $\mathbb{R}^{2,n}$. We will be very brief here and refer to [Wo] for a more detailed study (especially concerning de Sitter and anti-de Sitter spaces).

Minkowski components. Given a point $p \in \text{Ein}_n$, the complement of $C(p)$ in $\text{Ein}_n$ is a homogeneous open subset of $\text{Ein}_n$, which is conformally equivalent to Minkowski space $\mathbb{R}^{1,n-1}$. We say that this is the Minkowski component associated to $p$. In fact, we have an explicit formula for the stereographic projection identifying $\text{Ein}_n \setminus C(p)$ and $\mathbb{R}^{1,n-1}$ (see [CK], [Fr1]).

De Sitter and anti-de Sitter components. Just as Minkowski space arises by removing from $\text{Ein}_n$ the projectivization of a lightlike hyperplane, one also gets interesting open subsets by removing the projectivization of other (i.e. nondegenerate) hyperplanes.

If $P$ is some hyperplane of $\mathbb{R}^{2,n}$ with Lorentzian signature, then $\pi(P \cap C^{2,n})$ is a Riemannian sphere $S$ of codimension one. The canonical conformal structure of $\text{Ein}_n$ induces on this sphere the canonical Riemannian conformal structure. The stabilizer of $S$ in $O(2, n)$ is a group $G$ isomorphic to $O(1, n)$. The complement of $S$ in $\text{Ein}_n$ is a homogeneous open subset of $\text{Ein}_n$, conformally equivalent to the de Sitter space $dS_n$. Therefore $\mathbb{S}^{n-1}$, with its canonical conformal structure, appears as the conformal boundary of $dS_n$.

If $P$ is some hyperplane of $\mathbb{R}^{2,n}$ with signature $(2, n - 1)$, then the projection $\pi(P \cap C^{2,n})$ is a codimension one Einstein universe $E$. The stabilizer of $E$ in $O(2, n)$ is a subgroup isomorphic to $O(2, n - 1)$. The complement of $E$ is a homogeneous open subset of $\text{Ein}_n$, which is conformally equivalent to the anti-de Sitter space $AdS_n$. In this way we see $\text{Ein}_{n-1}$ as the conformal boundary of $AdS_n$.

Complement of a lightlike geodesic. What do we get if we remove from $\text{Ein}_n$ the projectivization of a maximal isotropic subspace of $\mathbb{R}^{2,n}$? Such subspaces are 2-planes, so that the resulting open set is the complement $\Omega_\Delta$ of a lightlike geodesic $\Delta \subset \text{Ein}_n$. Open sets like $\Omega_\Delta$ admit a natural foliation by degenerate hypersurfaces, and this foliation $\mathcal{H}_\Delta$ is preserved by the whole conformal group of $\Omega_\Delta$. This foliation can be described as follows: given a point $p \in \Delta$, we consider the lightcone $C(p)$ with vertex $p$. Since $\Delta$ is a lightlike geodesic, we have $\Delta \subset C(p)$. Now the intersection of $C(p)$ with $\Omega_\Delta$ is a degenerate hypersurface of $\Omega_\Delta$, diffeomorphic to $\mathbb{R}^{n-1}$. We call it $\mathcal{H}(p)$. If $p \neq p'$, $\mathcal{H}(p)$ and $\mathcal{H}(p')$ only intersect along $\Delta$, and the leaves of the foliation $\mathcal{H}_\Delta$ are just the $\mathcal{H}(p)$ for $p \in \Delta$.

2.5. The space $\mathbb{L}_n$ of lightlike geodesics of $\text{Ein}_n$. Since this space will appear naturally when we will define the limit set of a Lorentzian Kleinian group, we briefly describe it.

The stabilizer of a lightlike geodesic in $O(2, n)$ is a closed parabolic subgroup $P$, isomorphic to $(\mathbb{R} \times \text{SL}(2, \mathbb{R}) \times O(n - 2)) \ltimes \text{Heis}(2n - 3)$, where $\text{Heis}(2n - 3)$
denotes the Heisenberg group of dimension $2n - 3$. Thus $\mathbb{L}_n$ can be identified with the homogeneous space $O(2, n)/P$, which has dimension $2n - 3$.

Let $H \subset \mathbb{R}^{2,n}$ be a hyperplane with Lorentzian signature, and let $\Sigma$ be the projection of $H \cap C^{2,n}$ on $\text{Ein}_n$. The hypersurface $\Sigma$ is a codimension one Riemannian sphere of $\text{Ein}_n$. Now for any isotropic 2-plane $P \subset \mathbb{R}^{2,n}$, $P \cap H$ is 1-dimensional and isotropic. Equivalently, any lightlike geodesic of $\text{Ein}_n$ intersects $\Sigma$ in exactly one point. We get a well-defined submersion $p: \mathbb{L}_n \to \Sigma$. The fiber over $q \in \Sigma$ is the set of lightlike geodesics inside the lightcone $C(q)$. So, $\mathbb{L}_n$ is topologically an $S^{n-2}$ fiber bundle over $S^{n-1}$. Notice that $O(2, n)$ does not preserve the bundle structure.

3. Conformal dynamics on Einstein’s universe

3.1. Cartan decomposition of $O(2, n)$. From now on it will be more convenient to work in a basis of $\mathbb{R}^{2,n}$ for which $q^{2,n}(x) = -2x_1x_{n+2} + 2x_2x_{n+1} + x_2^2 + \cdots + x_n^2$. We call $O(2, n)$ the subgroup of $\text{GL}_{n+2}(\mathbb{R})$ preserving the form $q^{2,n}$. Let $A^+$ be a the subgroup of diagonal matrices in $O(2, n)$ of the form

$$
\begin{pmatrix}
\begin{array}{cccc}
e^\lambda & e^\mu & & \\
 & 1 & & \\
 & & \ddots & \\
 & & & e^{-\mu} \\
& & & e^{-\lambda}
\end{array}
\end{pmatrix},
$$

with $\lambda \geq \mu \geq 0$. Such an $A^+$ is usually called a Weyl chamber. The group $SO(2, n)$ can be written as the product $KA^+K$ where $K$ is a maximal compact subgroup of $SO(2, n)$. This decomposition is known as the Cartan decomposition of the group $SO(2, n)$ (compare [B], [IW]). Such a decomposition also exists for $O(2, n)$, with $K$ a compact set of $O(2, n)$. Moreover, for every $g \in O(2, n)$, there is a unique $a(g) \in A^+$ such that $g \in Ka(g)K$. The element $a(g)$ is called the Cartan projection of $g$. As a matrix it is written

$$
a(g) = 
\begin{pmatrix}
\begin{array}{cccc}
e^{\lambda(g)} & e^{\mu(g)} & & \\
 & 1 & & \\
 & & \ddots & \\
 & & & e^{-\mu(g)} \\
& & & e^{-\lambda(g)}
\end{array}
\end{pmatrix}.
$$
The reals $\lambda(g) \geq \mu(g) \geq 0$ are called the distortions of the element $g$ (associated with the given Cartan decomposition).

3.2. Qualitative dynamical description. We want to understand the possible dynamics for divergent sequences $(g_k)$ of $O(2, n)$ (i.e. sequences leaving every compact subset of $O(2, n)$). Our approach considers sequences $g_k(x_k)$, where $(x_k)$ is a converging sequence of $E_{1n}$. It is important to consider arbitrary such convergent sequences, not only constant sequences, in order to characterize proper actions. Recall that given a subgroup $\Gamma$ of homeomorphisms of a manifold $X$, one says that the action of $\Gamma$ on $X$ is proper if for all convergent sequences $(x_k)$ of $X$ and all divergent sequences $(g_k)$ of $\Gamma$, the sequence $g_k(x_k)$ does not have any accumulation point in $X$. Notice that there exist actions for which $g_k(x)$ diverges for all divergent $(g_k) \in \Gamma$ and all $x \in X$, but which are not proper (look, for example, at the action of a hyperbolic linear transformation of $SL(2, \mathbb{R})$ on the punctured plane $\mathbb{R}^2\setminus\{0\}$).

**Definition 1.** Let $(g_k)$ be a divergent sequence of homeomorphisms of a manifold $X$ (i.e. $(g_k)$ leaves any compact subset of $\text{Homeo}(X)$). For any point $x \in X$, we define the set

$$D((g_k))(x) = \bigcup_{x_k \to x} \text{accumulation points of } (g_k(x_k)).$$

The union is taken over all sequences converging to $x$.

Further, for any set $E \subset X$, $D((g_k))(E) = \bigcup_{x \in E} D((g_k))(x)$. Taking the union, over all divergent sequences $(g_k) \in \Gamma$, of the sets $D((g_k))(E)$, we get a closed set $D_\Gamma(E) \subset X$ that we call the dynamic set of $E$.

Notice that for two points $x$ and $y$ in $X$, $y \in D_\Gamma(x)$ if and only if $x \in D_\Gamma(y)$. We say in this case that $x$ and $y$ are dynamically related.

The interest of this definition for the study of actions of discrete groups can be illustrated by the following: let $\Gamma$ be a discrete group of $\text{Homeo}(X)$ acting on some open subset $\Omega \subset X$. Then the next result is easily proved.

**Proposition 1.** The group $\Gamma$ acts properly on $\Omega$ iff no two points of $\Omega$ are dynamically related.

Assuming that the action of $\Gamma$ on $\Omega$ is proper, we also have:

**Proposition 2.** If the action of $\Gamma$ on $\Omega$ has compact quotient, then every $x \in \partial\Omega$ must be dynamically related to some point $y$ of $\Omega$ (depending on $x$).

Now let $(g_k)$ be a divergent sequence of $O(2, n)$. We define $\lambda_k = \lambda(g_k)$, $\mu_k = \mu(g_k)$ and $\delta_k = \lambda_k - \mu_k$. We say that the sequence $(g_k)$ tends simply to infinity if
a) the three sequences $(\lambda_k), (\mu_k)$ and $(\delta_k)$ converge respectively to some $\lambda_\infty, \mu_\infty$ and $\delta_\infty$ in $\mathbb{R}$;

b) compact factors in the Cartan decomposition of $(g_k)$ both admit a limit in $K$.

Of course, every sequence tending to infinity admits some subsequence tending simply to infinity, so that we will restrict our study to these last ones. The sequences tending simply to infinity split into three categories:

(i) *Sequences with balanced distortions.* This name denotes the sequences $(g_k)$ for which $\lambda_\infty = \mu_\infty = +\infty$ and $\delta_\infty$ is finite.

(ii) *Sequences with bounded distortion.* This denotes the sequences $(g_k)$ for which $\mu_\infty \neq +\infty$.

(iii) *Sequences with mixed distortions.* This denotes the sequences $(g_k)$ for which $\lambda_\infty = \mu_\infty = \delta_\infty = +\infty$.

To each type corresponds, as we will see soon, distinct dynamical behaviours.

**Notation.** In the following we will use notations such as $C(p), \mathcal{H}_\Delta, \ldots$. We invite the reader to look at Section 2, where these notation were introduced.

For any set $E$ in $\mathbb{R}^{2,n}$, we use the notation $\tilde{\pi}(E)$ for $\pi(E \cap C^{2,n})$. If $y$ and $\varepsilon$ are two real numbers, we write $I_\varepsilon(y)$ for the closed interval $[y - \varepsilon, y + \varepsilon]$.

For every $x = (x_1, x_2, \ldots, x_{n+2})$ in $\mathbb{R}^{2,n}$, we define the $\varepsilon$-box centered at $x$ as $B_\varepsilon(x) = I_\varepsilon(x_1) \times I_\varepsilon(x_2) \times \cdots \times I_\varepsilon(x_{n+2})$.

For a sequence $(g_k)$ of $O(2,n)$ tending simply to infinity, we call $B_\varepsilon^\infty(x)$ the compact set obtained as the limit (for the Hausdorff topology) of the sequence of compact sets $g_k \circ \tilde{\pi}(B_\varepsilon(x))$ (this limit will always exist in the examples we will deal with).

Finally, we will often denote in the same way an element of $O(2,n)$ and the conformal transformation of $\text{Ein}_n$ that it induces.

**3.2.1. Dynamics with balanced distortions**

**Proposition 3.** Let $(g_k)$ be a sequence of $O(2,n)$ with balanced distortions. Then we can associate to $(g_k)$ two lightlike geodesics $\Delta^+$ and $\Delta^-$, called attracting and repelling circles of $(g_k)$, and two submersions $\pi_+: \text{Ein}_n \setminus \Delta^- \to \Delta^+$ (resp. $\pi_-: \text{Ein}_n \setminus \Delta^+ \to \Delta^-$), whose fibers are the leaves of $\mathcal{H}_\Delta^-$ (resp. $\mathcal{H}_\Delta^+$), such that the following holds.

For every compact subset $K$ of $\text{Ein}_n \setminus \Delta^-$ (resp. $\text{Ein}_n \setminus \Delta^+$), $D_{(g_k)}(K) = \pi_+(K)$ (resp. $D_{(g_k)^{-1}}(K) = \pi_-(K)$).

**Remark 1.** Before beginning the proof, let us remark that if $(g_k)$ has balanced distortions (resp. bounded distortion, resp. mixed distortions), it will be so for any compact
perturbation of \((g_k)\), i.e. any sequence \((l_k^{(1)} g_k l_k^{(2)})\) for \((l_k^{(1)})\) and \((l_k^{(2)})\) two converging sequences of \(O(2, n)\). In the same way the conclusions of the above proposition are not modified by a compact perturbation, even if of course \(\pi_{\pm} \) and \(\Delta^\pm\) are. So in the following (and also in Sections 3.2.2 and 3.2.3) we will restrict the proofs to the case where \((g_k)\) is a sequence of \(A^+\).

**Proof.** We restrict the proof to the case \(\lambda_k = \mu_k\), so that \(\delta_\infty = 0\).

We begin by defining \(\Delta^\pm\) and \(\pi^\pm\). Let us call \(P^\pm\) (resp. \(P^\mp\)) the 2-plane spanned by \(e_1\) and \(e_2\) (resp. \(e_{n+1}\) and \(e_{n+2}\)), and \(\Lambda^\pm\) (resp. \(\Lambda^-\)) the projection on \(\text{Ein}_n\) of these 2-planes. The space \(\mathbb{R}^{2,n}\) splits as a direct sum \(P_+ \oplus P_0 \oplus P_-\), where \(P_0\) is the span of \(e_3, \ldots, e_n\). This splitting defines a projection \(\tilde{\pi}_+\) (resp. \(\tilde{\pi}_-\)) from \(\mathbb{R}^{2,n}\) to the plane \(P^\mp\) (resp. \(P^-\)). The image \(\tilde{\pi}_+(x)\) is nonzero as soon as \(x\) is an isotropic vector of \(\mathbb{R}^{2,n}\) which is not in \(P^-\). Thus \(\tilde{\pi}_+\) induces a projection \(\pi_+\) of \(\text{Ein}_n \setminus \Delta^-\) on \(\Delta^+\) whose fibers are the projections on \(\text{Ein}_n\) of the fibers of \(\tilde{\pi}_+\). These are degenerate hyperplanes of \(\mathbb{R}^{2,n}\), defined as \(g_i^{\pm,n}\)-orthogonals of vectors of \(P^-\). So, the fibers of \(\pi_+\) are the intersections of \(\text{Ein}_n \setminus \Delta^-\) with the lightcones with vertex on \(\Delta^-\), i.e. the leaves of \(\mathcal{H}_\Delta^-\).

Now let us choose \(x\) such that \(\pi(x) \notin \Delta^+\). Since \(g_k \circ \tilde{\pi}_-(B_\varepsilon(x)) = \tilde{\pi}_-(I_{\varepsilon (x_1)} \times I_{\varepsilon (x_2)} \times I_{\varepsilon (x_3)} \times \cdots \times I_{\varepsilon (x_n)} \times I_{\varepsilon (x_n+1)} \times I_{\varepsilon (x_n+2)} \times \cdots \times I_{\varepsilon (x_n+2)})\), we obtain, for \(\varepsilon\) sufficiently small, that \(B_\varepsilon^\infty(x) = \tilde{\pi}(I_{\varepsilon (x_1)} \times I_{\varepsilon (x_2)} \times \{0\} \times \cdots \times \{0\})\).

We thus have \(B_\varepsilon^\infty(x) \subset \Delta^+\). Since \(\varepsilon\) is arbitrarily close to 0, for any sequence \((x_k)\) such that \(\pi(x_k)\) tends to \(\pi(x)\), we have \(\lim_{k \to \infty} g_k \circ \pi(x_k) = \pi(x, x_2, 0, \ldots, 0)\).

This concludes the proof. \(\Box\)

### 3.2.2. Dynamics with bounded distortion

**Proposition 4.** Let \((g_k)\) be a sequence of \(O(2, n)\) with bounded distortions. Then we can associate to \((g_k)\) two points \(p^+\) and \(p^-\) of \(\text{Ein}_n\), called attracting and repelling poles of \((g_k)\), and a diffeomorphism \(\hat{g}_\infty\) from the space of lightlike geodesics of \(C^- = C(p^-)\) in the space of lightlike geodesics of \(C^+ = C(p^+)\), conformal with respect to the natural conformal structure of these two spaces, such that we have:

(i) For all compact subset \(K\) inside \(\text{Ein}_n \setminus C^-\), we have \(D_{(g_k)}(K) = \{p^+\}\).

(ii) For a lightlike geodesic \(\Delta \subset C^-\) and a point \(x\) of \(\Delta\) distinct from \(p^-\), \(D_{(g_k)}(x)\) is the lightlike geodesic \(\hat{g}_\infty(\Delta)\).

(iii) The set \(D_{(g_k)}(p^-)\) is the whole of \(\text{Ein}_n\).

The cones \(C^+\) and \(C^-\) are called attracting and repelling cones of \((g_k)\).

**Remark 2.** The dynamical pattern of the sequence \((g_k)\) is obtained by switching the \(+\)'s and the \(-\)'s in the statement. This remark holds also for Proposition 5.
Proof. Following Remark 1, we do the proof for a sequence \((g_k)\) of \(A^+\), with \(\lim_{k \to \infty} \lambda_k = +\infty\).

Let \(p^+ = \pi(e_1)\), \(p^- = \pi(e_{n+2})\), \(C^+ = \tilde{\pi}((e_1)^\perp)\), \(C^- = \tilde{\pi}((e_{n+2})^\perp)\).

Let us first remark that if \(x_1 \neq 0\), then clearly \(B^\infty_\varepsilon(x) = p^+\). This proves (i), as well as (iii), passing to the complement.

If \(\pi(x) \in C^-\) and if \(\varepsilon\) is sufficiently small, we get that \(B^\infty_\varepsilon(x) = \tilde{\pi}(\mathbb{R} \times I^\mu_{\infty}(x_2) \times I^\varepsilon(x_3) \times \cdots \times I^\varepsilon(x_n) \times I^\varepsilon_{-\mu}(x_{n+1}) \times \{0\})\).

The lightlike geodesics of \(C^+\) and \(C^-\) are parametrized by a sphere \(S^{n-2}\) corresponding to isotropic directions of the space spanned by \(e_2, \ldots, e_{n+1}\).

We define \(\hat{g}_\infty\) as the element of \(O(1, n-1)\) given by
\[
\hat{g}_\infty = \begin{pmatrix}
eu{1} & 1 \\
\vdots & \ddots \\
0 & \cdots & e^{-\mu_\infty}
\end{pmatrix}.
\]

The spaces of lightlike geodesics of \(C^+\) and \(C^-\) have a canonical conformal Riemannian structure, and we see that the map \(\hat{g}_\infty\) is a conformal diffeomorphism between these two spaces.

By the above formula, if \(\pi(x_k)\) converges to \(\pi(x)\), the accumulation points of the sequence \(g_k(\pi(x_k))\) are in every \(B^\infty_\varepsilon(x)\), for arbitrary small \(\varepsilon\). The intersection of all \(B^\infty_\varepsilon(x)\) is \(\tilde{\pi}(\mathbb{R} \times \{e^\mu_{\infty}x_2\} \times \{x_3\} \times \cdots \times \{x_n\} \times \{e^{-\mu_{\infty}}x_{n+1}\} \times \{0\})\), i.e. the image by \(\hat{\pi}\) of the lightlike geodesic passing through \(p^-\) and \(\pi(x)\). Conversely, every point \(\pi(y)\) of this geodesic is in the Hausdorff limit of \(g_k \circ \pi(B_\varepsilon(x))\). Hence, there exists a sequence \(x_k^\varepsilon\) of \(B_\varepsilon(x)\) with \(\lim_{k \to \infty} g_k \circ \pi(x_k^\varepsilon) = \pi(y)\). Let \(\varepsilon_k\) be a sequence tending to \(0\). Then \(\lim_{k \to \infty} g_k \circ \pi(x_{n_k}^\varepsilon) = \pi(y)\) for some sequence of integers \(n_k\), and \(\pi(x_{n_k}^\varepsilon)\) tends to \(\pi(x)\). This concludes the proof of (ii). \(\square\)

3.2.3. Mixed dynamics

Proposition 5. Let \((g_k)\) be a sequence of \(O(2, n)\) with mixed distortions. Then we can associate to \((g_k)\) two points \(p^+\) and \(p^-\), called attracting and repelling poles of the sequence, as well as two lightlike geodesics \(\Delta^+\) et \(\Delta^-\) (called attracting and repelling circles), with the inclusions \(p^+ \in \Delta^+ \subseteq C^+ = C(p^+)\) and \(p^- \in \Delta^- \subseteq C^- = C(p^-)\), such that the following properties hold:

(i) For every compact subset \(K\) inside \(\text{Ein}_n \setminus C^-\), the set \(D_{(g_k)}(K)\) is \(\{p^+\}\).

(ii) If \(x\) is a point of \(C^-\) not on \(\Delta^-\), then \(D_{(g_k)}(x)\) is the lightlike geodesic \(\Delta^+\).

(iii) If \(x\) is a point of \(\Delta^-\) distinct from \(p^-\), then \(D_{(g_k)}(x)\) is the attracting cone \(C^+\).

(iv) The set \(D_{(g_k)} \ p^-\) is the whole of \(\text{Ein}_n\).
The cones $C^+$ and $C^-$ are called *attracting* and *repelling cones* of the sequence $(g_k)$.

**Proof.** Once again we suppose that $(g_k)$ is in $A^+$. Let $p^+ = \pi(e_1)$, $p^- = \pi(e_{n+2})$, $C^+ = \tilde{\pi}((e_1)^\perp)$, $C^- = \tilde{\pi}((e_{n+2})^\perp)$. The circle $\Delta^+$ (resp. $\Delta^-$) is the projection of the 2-plane spanned by $e_1$ and $e_2$ (resp. $e_{n+1}$ and $e_{n+2}$). We do not show (i) and (iv), the proof being exactly the same as for Proposition 4.

If $\pi(x) \in C^-$, but $\pi(x) \notin \Delta^-$, then $x_1 = 0$, but $x_2 \neq 0$. In this case we get $B^\infty_{\tilde{\pi}}(x) = \tilde{\pi}(\mathbb{R} \times I_e(x_2) \times \{0\} \times \cdots \times \{0\})$, that is to say $\Delta^+$.

The intersection of all the $B^\infty_{\tilde{\pi}}(x)$ is $\tilde{\pi}(\mathbb{R} \times \{x_2\} \times \{0\} \times \cdots \times \{0\})$, i.e. the lightlike geodesic $\Delta^+$. The fact that $D(g_k)(\pi(x)) = \Delta^+$ is proved exactly as in Proposition 4.

As previously, we get $D(g_k)(\pi(x)) = \Delta^+$. \(\square\)

**Remark 3.** Notice that different configurations for the dynamical elements described above can occur. For example, attracting and repelling circles of a dynamics with balanced or mixed distortions can intersect, or even be the same. In fact, all the possible configurations can occur.

### 4. About the limit set of a Lorentzian Kleinian group

#### 4.1. Definition of the limit set

Given a Kleinian group $\Gamma$ on a manifold $X$, it is quite natural to ask if there is in some sense a “canonical” open set $\Omega \subset X$ on which $\Gamma$ acts properly. For example, any Kleinian group $\Gamma$ on the sphere $S^n$ admits a limit set $\Lambda_\Gamma$ and the open set $\Omega_\Gamma = S^n \setminus \Lambda_\Gamma$ is distinguished, since it is the only maximal open subset on which $\Gamma$ acts properly. The nice properties of the limit set of a Kleinian group on $S^n$ rest essentially on the fact that the Möbius group $O(1, n + 1)$ is a convergence group on $S^n$. We just saw in the previous section that $O(2, n)$ is quite far from being a convergence group on $\text{Ein}_n$, but we would nevertheless like to define a limit set $\Lambda_\Gamma$ associated to a given discrete group $\Gamma \subset O(2, n)$. We require that such a limit set have at least the two following properties:

(i) $\Lambda_\Gamma$ is a $\Gamma$-invariant closed subset of $\text{Ein}_n$.

(ii) The action of $\Gamma$ on $\Omega_\Gamma = \text{Ein}_n \setminus \Lambda_\Gamma$ is properly discontinuous.

**Definition 2.** Given $\Gamma$ discrete in $O(2, n)$, we define $\delta_\Gamma$ (resp. $\mathcal{T}_\Gamma$) the set of sequences $(\gamma_k)$ of $\Gamma$, tending simply to infinity, with mixed or balanced distortions (resp. with bounded distortion). If $(\gamma_k)$ is a sequence of $\delta_\Gamma$ (resp. $\mathcal{T}_\Gamma$), we call $\Delta^+(\gamma_k)$ and $\Delta^-(\gamma_k)$ (resp. $C^+(\gamma_k)$ and $C^-((\gamma_k)$) its attracting and repelling circles (resp. attracting and repelling cones).
**Definition 3.** We define the limit set of a discrete $\Gamma \subset O(2, n)$ as

$$\Lambda_\Gamma = \Lambda_\Gamma^{(1)} \cup \Lambda_\Gamma^{(2)},$$

where

$$\Lambda_\Gamma^{(1)} = \bigcup_{(\gamma_k) \in \delta_\Gamma} \Delta^+(\gamma_k) \cup \Delta^-(\gamma_k)$$

and

$$\Lambda_\Gamma^{(2)} = \bigcup_{(\gamma_k) \in T_\Gamma} C^+(\gamma_k) \cup C^-(\gamma_k).$$

**Notation.** The complement of $\Lambda_\Gamma$ in Ein$_n$ is denoted by $\Omega_\Gamma$.

It is clear that $\Lambda_\Gamma$ is closed and $\Gamma$-invariant. Let us remark that $\Lambda_\Gamma$ is a union of lightlike geodesics, so that it also defines a closed $\Gamma$-invariant subset $\tilde{\Lambda}_\Gamma \subset L_n$.

From the dynamical properties stated in the previous section, one checks easily that no pair of points in $\Omega_\Gamma$ can be dynamically related, so that the action of $\Gamma$ on $\Omega_\Gamma$ is proper.

### 4.2. Lorentzian Kleinian groups of the first and the second type.

Until now we did not focus on a fundamental difference between the action of $O(1, n+1)$ on $\mathbb{S}^n$ and that of $O(2, n)$ on Ein$_n$. Although any discrete group $\Gamma \subset O(1, n+1)$ automatically acts properly on $\mathbb{H}^{n+1}$, it is not true in general that a discrete $\Gamma \subset O(2, n)$ does so on AdS$_{n+1}$. This motivates the following distinction between subgroups of $O(2, n)$.

**Definition 4.** A discrete group $\Gamma$ of $O(2, n)$ is of the **first type** if it acts properly on AdS$_{n+1}$. If not, it is said to be of the **second type**.

Notice that this terminology has no connection with the denomination of being of **first kind** and of **second kind** for the standard Kleinian groups on the sphere.

The previous dichotomy has a nice translation into dynamical terms due to the next result.

**Proposition 6.** A Kleinian group $\Gamma$ of $O(2, n)$ is of the first type if and only if it does not admit any sequence $(\gamma_k)$ with bounded distortion.

**Proof.** We endow $\mathbb{R}^{2,n+1}$ with the quadratic form $q^{2,n+1}(x) = -2x_1x_{n+2} + 2x_2x_{n+1} + x_3^2 + \cdots + x_n^2 + x_{n+3}^2$ and call $e_1, \ldots, e_{n+3}$ the canonical basis. The subgroup of $O(2, n+1)$ leaving invariant the subspace spanned by the first $n+2$ basis vectors can be canonically identified with $O(2, n)$. This identification defines an embedding $j$ from $O(2, n)$ into $O(2, n+1)$. The action of $j(O(2, n))$ on Ein$_{n+1}$ leaves invariant a codimension one Einstein universe that we call Ein$_n$. As we saw in the introduction,
the complement of Ein$_n$ in Ein$_{n+1}$ is conformally equivalent to the anti-de Sitter space AdS$_{n+1}$.

Let us consider some $g$ in O(2, n). In the basis $e_1, \ldots, e_{n+3}$, $j(g) = \begin{pmatrix} g & \mathbf{0} \\ \mathbf{0} & 1 \end{pmatrix}$, so that when we perform the Cartan decomposition of $j(g)$, we find the same distortions as for $g$.

Suppose now that $\Gamma$ admits some sequence $(\gamma_k)$ with bounded distortion. By the remark above, $j(\gamma_k)$ has also bounded distortion as a sequence of O(2, $n+1$). We call $C^+$ and $C^-$ its attracting and repelling cones in Ein$_{n+1}$. By Proposition 4, $D(\gamma_k)(C^- \cap \text{AdS}_{n+1}) = C^+ \cap \text{AdS}_{n+1}$. Therefore we can find two points of AdS$_{n+1}$ which are dynamically related, so that the action of $(\gamma_k)$ on AdS$_{n+1}$ cannot be proper (Proposition 1).

Conversely, let us consider some sequence $(\gamma_k)$ tending simply to infinity and with balanced or mixed distortions. Then the sequence $j(\gamma_k)$ has the same properties. Let us call $\Delta^+$ and $\Delta^-$ the attracting and repelling circles of this latter sequence. Looking at the matrix expressions, it is clear that $\Delta^+ \subset \text{Ein}_n$ and $\Delta^- \subset \text{Ein}_n$. By Propositions 3 and 5, $D(\gamma_k)(x) \subset \text{Ein}_n$ for any point $x \in \text{AdS}_{n+1}$. So, if we assume that $\Gamma$ has no sequence with bounded distortion, we get $D(\gamma_k)(x) \subset \text{Ein}_n$ for any point $x \in \text{AdS}_{n+1}$. Using Proposition 1, we get that $\Gamma$ acts properly on AdS$_{n+1}$. $\square$

4.3. Limit set of a group of the first type: proof of Theorem 1. Since $\Gamma$ is of the first type, $\Lambda_\Gamma$ is also the limit set of $\Gamma$, regarded as a subgroup of O(2, $n+1$) acting on Ein$_{n+1}$. The complement of this limit set in Ein$_{n+1}$ is precisely $\Omega_\Gamma \cup \text{AdS}_{n+1}$, so that (i) of the theorem is clear.

To prove (ii), let us suppose that $\Gamma$ acts properly on some $\Omega \cup \text{AdS}_{n+1}$ with $\Omega$ not included in $\Omega_\Gamma$. Then there is a sequence $(\gamma_k)$ of $\Gamma$ (with balanced or mixed distortions) such that $\Delta^- (\gamma_k)$ meets $\Omega$.

Lemma 1. Let $\Gamma$ be a discrete group of O(2, n) acting properly on some open set $\Omega$. Then for any sequence $(\gamma_k)$ of $\Gamma$ with balanced distortions, neither $\Delta^+(\gamma_k)$ nor $\Delta^-(\gamma_k)$ meets $\Omega$.

Proof. Suppose on the contrary that for some $(\gamma_k)$ with balanced distortions, we have $\Delta^+(\gamma_k) \cap \Omega \neq \emptyset$. From Proposition 3, we infer that the set $D(\gamma_k)(\Delta^+(\gamma_k) \cap \Omega)$ contains a lightlike geodesic $\Delta$ in its interior. So, there is a tubular neighbourhood $U$ of $\Delta$ contained in Ext($\Omega$) (Ext($\Omega$) denotes the complement of $\Omega$ in Ein$_n$). But we also infer from Proposition 3 that for any $\Delta$ not meeting $\Delta^-(\gamma_k)$, we have $\lim_{k \to +\infty} \gamma_k(\Delta) = \Delta^+(\gamma_k)$. As a consequence, any lightlike geodesic of Ext($\Omega$) has to cut $\Delta^-(\gamma_k)$. Since all the lightlike geodesics included in $U$ cannot all meet $\Delta^-(\gamma_k)$ we get a contradiction. $\square$

The lemma above tells us that the sequence $(\gamma_k)$ has mixed distortions. For any point $x \in \Delta^-(\gamma_k) \cap \Omega$, we have $D(\gamma_k)(x) = C^+(\gamma_k)$. Since $C^+(\gamma_k)$ meets AdS$_{n+1}$,
we get pairs of points in $\Omega \cup \text{AdS}_{n+1}$ which are dynamically related, and the action cannot be proper by Proposition 1.

**Remark 4.** For $\Gamma$ Kleinian of the first type, the manifold $\Omega_\Gamma / \Gamma$ appears as the conformal boundary of the complete anti-de Sitter manifold $\text{AdS}_{n+1} / \Gamma$ (see [Fr4] for more details on this point).

To prove (iii), we begin by showing that $\tilde{\Lambda}_\Gamma \subset \mathbb{L}_n$ is a minimal set. This is in fact a particular case of a general result of Benoist ([B]), but we give a simple proof.

Let $\Lambda$ be a closed $\Gamma$-invariant subset of $\mathbb{L}_n$. Any sequence $(\gamma_k)$ tending simply to infinity in $\Gamma$ has either mixed or balanced distortions. As a simple consequence of Propositions 3 and 5, we get that if $\Delta_{\gamma_k}$ is a lightlike geodesic of $\text{Ein}_n$ which does not meet $\Delta^-(\gamma_k)$, then $\lim_{k \to +\infty} \gamma_k(\Delta) = \Delta^+(\gamma_k)$. So, if for any sequence $(\gamma_k)$ as above, no geodesic of $\Lambda$ meets $\Delta^-(\gamma_k)$, we have $\Lambda_\Gamma \subset \Lambda$, and we are done.

On the contrary, if for some $(\gamma_k)$, all the geodesics of $\tilde{\Lambda}$ meet $\Delta^-(\gamma_k)$, we claim that $\Gamma$ cannot be Zariski dense. Indeed, by Zariski density, $\Gamma$ cannot leave $\Delta^-(\gamma_k)$ invariant. So, let us choose $\gamma \in \Gamma$ such that $\gamma(\Delta^-(\gamma_k)) \neq \Delta^-(\gamma_k)$. If $\gamma(\Delta^-(\gamma_k))$ and $\Delta^-(\gamma_k)$ are disjoint, the set of lightlike geodesics meeting both $g(\Delta^-(\gamma_k))$ and $\Delta^-(\gamma_k)$ is contained in a 2-dimensional Einstein universe, which have to be fixed by $\Gamma$: a contradiction with the Zariski density of $\Gamma$.

If $g(\Delta^-(\gamma_k))$ and $\Delta^-(\gamma_k)$ meet in one point $p$, then any lightlike geodesic meeting both $g(\Delta^-(\gamma_k))$ and $\Delta^-(\gamma_k)$ has to contain $p$. Indeed, due to the fact that the quadratic form $q_{2,n}$ cannot have some 3-dimensional isotropic subspace, there is no nontrivial triangle of $\text{Ein}_n$, whose edges are pieces of lightlike geodesics. We infer that $\Gamma$ has to fix the lightcone $C(p)$ and we get once again a contradiction.

We can now show that $\Omega_\Gamma$ is the maximal open set on which the action of $\Gamma$ is proper. Suppose that $\Gamma$ acts properly on $\Omega$ which is not included in $\Omega_\Gamma$. We call $\Lambda$ the complement of $\Omega$ in $\text{Ein}_n$. Since $\Delta_\Gamma \not\subset \Lambda$, there is a sequence $(\gamma_k)$ tending simply to infinity in $\Gamma$ with $\Delta^+(\gamma_k) \cap \Omega \neq \emptyset$.

**Lemma 2.** If an infinite Kleinian group $\Gamma \subset \text{O}(2,n)$ acts properly on some open subset $\Omega$, then the complement $\Lambda$ of $\Omega$ in $\text{Ein}_n$ contains a lightlike geodesic.

**Proof.** Let us pick a sequence $(\gamma_k)$ tending simply to infinity in $\Gamma$. Suppose first that $(\gamma_k)$ has mixed dynamics. Suppose that $\Delta^-(\gamma_k)$ meets $\Omega$ at a point $x$ (if $\Delta^-(\gamma_k) \cap \Omega = \emptyset$, we are done). By properness, $D_{(g_k)}(x) \cap \Omega = \emptyset$. But $D_{(g_k)}(x) = C^+(g_k)$, which contains infinitely many lightlike geodesics, and the conclusion holds.

Also, if $(g_k)$ has balanced (resp. bounded) distortions, the dynamic set $D_{(g_k)}x$ of $x \in \Delta^-(\gamma_k)$ (resp. $x \in C^-(\gamma_k)$) contains infinitely many lightlike geodesics. The proof works thus in the same way. \qed
Now let us look at the lightlike geodesics of $\Lambda$. Since by Zariski density, $\Gamma$ cannot fix a finite family of lightlike geodesics, there are infinitely many lightlike geodesics in $\Lambda$. But all these geodesics have to meet $\Delta^-(\gamma_k)$, because if some $\Delta$ does not, $$\lim_{k \to +\infty} \Delta^{-}(\gamma_k) = \Delta^{-}(\gamma_k).$$ A contradiction with $\Delta^-(\gamma_k) \cap \Omega \neq \emptyset$. Now, we conclude as for proving the minimality property of $\hat{\Lambda}_{\Gamma}$: all the lightlike geodesics of $\Lambda$ are in the same $\Gamma$-invariant Einstein torus, or the same $\Gamma$-invariant lightcone, and we get a contradiction with the Zariski density of $\Gamma$.

5. Some examples of Lorentzian Kleinian groups

5.1. Examples arising from structures with constant curvature. In Lorentzian geometry, a completeness result ensures that any compact Lorentzian manifold with constant sectional curvature is obtained as a quotient $\mathbb{R}^{1,n-1}/\Gamma$ or $\text{AdS}_n/\Gamma$, where $\Gamma$ is a discrete group of Lorentzian isometries. This deep theorem was first proved for the case of curvature zero by Carrière in [Ca], and generalized by Klingler in [Kl] (note that compact Lorentzian manifolds cannot have curvature +1). Another result, known as finiteness of level (see [KR], [Ze]), ensures that any compact quotient $\text{AdS}_n/\tilde{\Gamma}$ (where $\tilde{\Gamma}$ is a discrete group of isometries) is in fact, up to finite cover, a quotient $\text{AdS}_n/\Gamma$. Since $\mathbb{R}^{1,n-1}$ and $\text{AdS}_n$ both embed conformally into $\text{Ein}_n$ (see Section 2), by Theorem 4 we get that any compact Lorentzian structure with constant curvature is (up to finite cover) uniformized by a Lorentzian Kleinian groups. Moreover, in this case the structure of the groups involved is fairly well understood, due to [CaD], [Sa] and [Ze].

5.2. Examples arising from flat CR-geometry. Let us consider the complex vector space $\mathbb{C}^{n+1}$, endowed with the hermitian form $h^{1,n-1}(z) = -|z_1|^2 + |z_2|^2 + |z_3|^2 + \cdots + |z_{n+1}|^2$. We consider $C^{1,n}_\mathbb{C}$, the lightcone defined as $\{z \in \mathbb{C}^{n+1} | h^{1,n}(z) = 0\}$, and call $\Omega^-$ the open set $\{z \in \mathbb{C}^{n+1} | h^{1,n}(z) < 0\}$. If we project $\Omega^-$ on the complex projective space $\mathbb{CP}^n$. If we project $C^{1,n}_\mathbb{C}$ minus the origin on $\mathbb{CP}^n$, we get a sphere $S^{2n-1}$, naturally endowed with a CR-structure. This CR-sphere can be seen at the infinity of $\mathbb{H}^n_\mathbb{C}$. If, instead of looking at the complex directions of $C^{1,n}_\mathbb{C}$, we consider the quotient $C^{1,n}_\mathbb{C}/\mathbb{R}^*$ of $C^{1,n}_\mathbb{C}$ by the real homotheties, then the space that we get is Einstein’s universe of dimension $2n$. In other words, there is a fibration $f: \text{Ein}_{2n} \to S^{2n-1}$ whose fibers are circles. The fibration is preserved by the group $U(1,n)$, which acts on $\text{Ein}_{2n}$ as a subgroup of $O(2,2n)$. If $Z$ denotes the center of $U(1,n)$ (homotheties by complex numbers of modulus 1), then the fibers of $f$ are exactly the orbits of $Z$ on $\text{Ein}_{2n}$. These orbits are lightlike geodesics.

Proposition 7. If $\Gamma \in U(1,n)$ is a discrete group, whose projection $\tilde{\Gamma}$ on $\text{PU}(1,n)$ acts properly discontinuously on $\tilde{\Omega} \subset S^{2n-1}$, then $\Gamma$ is a Kleinian group of $\text{Ein}_{2n}$.
and acts properly discontinuously on \( \Omega = f^{-1}(\hat{\Omega}) \). If \( \hat{G} \) acts with compact quotient on \( \hat{\Omega} \), so does \( \Gamma \) on \( \Omega \).

**Remark 5.** The group \( \text{PU}(1, n) \) acting on \( S^{2n-1} \) is a convergence group, and there is a good notion of limit set for a discrete group \( \hat{G} \) as above (see for example [A]). In fact, it is not difficult to check that the Lorentzian Kleinian groups \( \Gamma \) built as in Proposition 7 are of the first type. Their limit set is just the preimage by \( f \) of the limit set \( \hat{\Lambda}_1 \) of \( \hat{G} \) on \( S^{2n-1} \).

To illustrate this case, let us mention the two following examples.

**Example 1.** We write each \( z \in \mathbb{C}^{n+1} \) as \( z = (x, y) \) with \( x \) and \( y \) in \( \mathbb{R}^n \). We identify the real hyperbolic space \( \mathbb{H}^n_{\mathbb{R}} \) with the set of points \( (x, y) \) with \( -x_1^2 + x_2^2 + \cdots + x_{n+1}^2 = -1 \) and \( x_1 > 0 \). If \( (x, y) \) is moreover in the unit tangent bundle of \( \mathbb{H}^n_{\mathbb{R}} \), it satisfies the following two extra equations:

\[
-x_1 y_1 + x_2 y_2 + \cdots + x_n y_n = 0, \\
-y_1^2 + y_2^2 + \cdots + y_{n+1}^2 = 1.
\]

Projectivising, we get an open subset \( \hat{\Omega} \subset S^{2n-1} \). In fact \( \hat{\Omega} \) is precisely \( S^{2n-1} \) minus an \((n-1)\)-dimensional sphere \( \Sigma \) (the projection on \( S^{2n-1} \) of the set \( \{ z = (x, 0) | -x_1^2 + x_2^2 + \cdots + x_{n+1}^2 = 0 \} \)).

Now the subgroup \( G = O(1, n) \) of real matrices in \( U(1, n) \) acts on \( S^{2n-1} \) and preserves \( \hat{\Omega} \). Identifying \( \hat{\Omega} \) with \( T^1 \mathbb{H}^n_{\mathbb{R}} \), we get that \( G \) acts properly and transitively on \( \hat{\Omega} \). As a consequence we have the following

**Fact.** Any discrete group \( \Gamma \) in \( O(1, n) \) acts properly discontinuously on \( \hat{\Omega} \). Considered as a subgroup of \( O(2, 2n) \) it yields a Kleinian group acting on \( \text{Ein}_{2n} \).

The Kleinian manifold \( \Omega / \Gamma \) obtained in this way are circle bundles over \( T^1(N) \), where \( N \) is the hyperbolic manifold \( \mathbb{H}^n_{\mathbb{R}} / \Gamma \).

**Example 2.** Inside \( U(1, n) \) there is a group \( G \) isomorphic to the Heisenberg group of dimension \( 2n-1 \). The group \( G \) fixes a point \( p_\infty \) on \( S^{2n-1} \) and acts simply transitively on the complement of this point. By Proposition 7, any discrete group in \( G \) will yield a Lorentzian Kleinian group, acting properly on the complement of a lightlike geodesic. The Kleinian manifolds obtained in this way will be circle bundles over nilmanifolds.

**5.3. Subgroups of \( O(1, r) \times O(1, s) \).** We still endow \( \mathbb{R}^{2,n} \) with the quadratic form \( q^{2,n}(x) = -2x_1 x_{n+2} + 2x_2 x_{n+1} + x_2^2 + \cdots + x_n^2 \), and we consider an orthogonal splitting \( \mathbb{R}^{2,n} = E_1 + E_2 \) with \( E_1 \) and \( E_2 \) two spaces of signature \((1, r)\) and
(1, s) respectively \((r \neq 0, s \neq 0 \text{ and } r + s = n)\). We suppose also \(r \leq s\). For example, we take \(E_1 = (e_1, e_3, \ldots, e_{3+r-2}, e_{n+2})\) and \(E_2 = (e_2, e_{3+r-1}, \ldots, e_{n+1})\).

The subgroup \(G\) of \(O(2, n)\) preserving this splitting is isomorphic to the product \(O(1, r) \times O(1, s)\). Before describing some examples of Kleinian groups in \(G\), let us say a few words about the geometric meaning of this splitting on \(\text{Ein}_n\).

**Lemma 3.** We can write \(\text{Ein}_n\) as a union \(\Omega_1 \cup \Omega_2 \cup \Sigma\). The set \(\Omega_1\) (resp. \(\Omega_2\)) is open, \(G\)-invariant, homogeneous under the action of \(G\), and conformally equivalent to the product \(dS_r \times \mathbb{H}^s\) (resp. \(\mathbb{H}^r \times dS_s\)). \(\Sigma\) is a singular, degenerate \(G\)-invariant hypersurface.

**Proof.** We call \(\pi_1\) and \(\pi_2\) the projections of \(\mathbb{R}^{2,n}\) on \(E_1\) and \(E_2\), respectively. The projection of vectors \(u = (v, w)\) of \(\mathbb{R}^{2,n}\), for which both \(v = \pi_1(u)\) and \(w = \pi_2(u)\) are isotropic, gives the hypersurface \(\Sigma\). We will say more about it later.

The vectors \(u = (v, w)\), for which neither \(v\) nor \(w\) is isotropic, are of two kinds.

Those for which \(q^{2,n}(v) > 0\). Since we work projectively, we can suppose that \(q^{2,n}(v) = 1\) and \(q^{2,n}(w) = -1\). In a further quotient by \(-\text{Id}\) these vectors project on the product \(dS_r \times \mathbb{H}^s\). They constitute the open set \(\Omega_1\).

Those for which \(q^{2,n}(v) < 0\). These vectors project on a product \(\mathbb{H}^r \times dS_s\) and constitute the open set \(\Omega_2\).

The hypersurface \(\Sigma\) can be regarded as the conformal boundary of the spaces \(dS_r \times \mathbb{H}^s\) and \(\mathbb{H}^r \times dS_s\). Let us describe it more precisely. The isotropic vectors \((v, w)\) of \(\mathbb{R}^{2,n}\), for which \(v\) and \(w\) are isotropic, split themselves into two sets. Those for which either \(v\) or \(w\) is zero. Their projectivisation gives two Riemannian spheres \(\Sigma_1\) and \(\Sigma_2\) of dimension \((r - 1)\) and \((s - 1)\) respectively.

Those for which \(v\) and \(w\) are nonzero project on the product of the projectivisation of the lightcone of \(E_1\) by the lightcone of \(E_2\), namely \(S^{r-1} \times \mathbb{C}^{1,s}\). So \(\Sigma\) minus \(\Sigma_1 \cup \Sigma_2\) has two connected components, each of which is diffeomorphic to \(S^{r-1} \times S^{s-1} \times \mathbb{R}\). One can check that \(\Sigma\) is obtained as the union of the lightlike geodesics intersecting both \(\Sigma_1\) and \(\Sigma_2\).

We now give some examples of Kleinian groups in \(G\).

**Example 3.** Let us take a discrete group \(\hat{\Gamma}\) inside \(O(1, r)\) and any representation \(\rho\) of \(\hat{\Gamma}\) inside \(O(1, s)\). We call \(\Gamma_\rho = \text{Graph}(\hat{\Gamma}, \rho) = \{(\hat{\gamma}, \rho(\hat{\gamma})) | \hat{\gamma} \in \hat{\Gamma}\}\). Then \(\Gamma_\rho\) is a Lorentzian Kleinian group of \(O(2, n)\). Indeed, its action on \(\Omega_2 = \mathbb{H}^r \times dS_s\) is clearly proper. Let us say a little bit more about the limit set of these groups. We call \(\Lambda_{\hat{\Gamma}}\) the limit set of the group \(\hat{\Gamma}\) on the sphere \(\Sigma_1\).

**Case a):** \(\rho\) is injective with discrete image. A sequence \((\gamma_k)\) of \(\Gamma_\rho\) can be written as a matrix \(\left(\begin{array}{c}
\hat{\gamma}_k \\
\rho(\hat{\gamma}_k)\end{array}\right)\). If \((\gamma_k)\) tends simply to infinity, so does the sequence \((\hat{\gamma}_k)\) (resp. \(\rho(\hat{\gamma}_k)\)) in \(O(1, r)\) (resp. in \(O(1, s)\)). We thus see that \((\gamma_k)\) has either mixed
or balanced distortions. In particular, the group $\Gamma_\rho$ is always of the first type in this case.

The attracting and repelling circles of $(\gamma_k)$ can be described as follows. Since the sequence $(\hat{\gamma}_k)$ (resp. $\rho(\hat{\gamma}_k)$) tends simply to infinity in $O(1, r)$ (resp. $O(1, s)$), it has two attracting and repelling poles $p^+(\hat{\gamma}_k)$ and $p^-(\hat{\gamma}_k)$ (resp. $p^+(\rho(\hat{\gamma}_k))$ and $p^-(\rho(\hat{\gamma}_k))$) on $\Sigma_1$ (resp. $\Sigma_2$). Then $\Delta^+(\gamma_k)$ (resp. $\Delta^-(\gamma_k)$) is simply the lightlike geodesic of $\text{Ein}_n$ joining $p^+(\hat{\gamma}_k)$ and $p^+(\rho(\hat{\gamma}_k))$ (resp. $p^-(\hat{\gamma}_k)$ and $p^-(\rho(\hat{\gamma}_k))$). In particular, the limit set $\Lambda_1/\Gamma_\rho$ is a closed subset of $\Sigma_1$ (strictly included in $\Sigma$ if $\Lambda_{\hat{\Gamma}} \neq \Sigma_1$).

An interesting subcase arises when we take for $\hat{\Gamma}$ a cocompact lattice in $O(1, 2)$, and a quasi-fuchsian representation $\rho: \hat{\Gamma} \to O(1, s)$ ($s \geq 2$). The limit set of $\rho(\hat{\Gamma})$ on $\Sigma_2$ is a topological circle, and we get for the limit set $\Lambda_{\Gamma_\rho}$ a topological torus. One can prove moreover (which is omitted here) that the action of $\Gamma_\rho$ is cocompact on the complement of its limit set.

Case b): $\rho$ is not injective with discrete image. In this case there is a sequence $(\gamma_k)$ tending simply to infinity in $\Gamma_\rho$ such that $\rho(\hat{\gamma}_k)$ is bounded. Such a sequence $(\gamma_k)$ has bounded distortion, and the group $\Gamma_\rho$ is of the second type. The attracting and repelling poles $p^+(\gamma_k)$ and $p^-(\gamma_k)$ are both on $\Sigma_1$. In fact they are the attracting and repelling poles of $(\hat{\gamma}_k)$ (acting as a sequence of $O(1, r)$ on $\Sigma_1$). In this case the limit set $\Lambda_{\Gamma_\rho}$ is just the union of lightcones with vertex on $\Lambda_{\hat{\Gamma}}$.

6. About Klein’s combination theorem

The examples of Kleinian groups given so far are not completely satisfactory, since they arise from geometrical contexts such as Lorentzian spaces with constant curvature or flat CR-geometry, and in some way are not “typical” of conformally flat Lorentzian geometry. For instance, we still do not have examples of Zariski dense Kleinian groups on $\text{Ein}_n$. One way to construct other classes of examples is to combine two existing Lorentzian Kleinian groups to get a third one. In the theory of Kleinian groups on the sphere this kind of construction is achieved on the basis of the celebrated Klein’s combination theorem ([A], [M]). We now state a generalized version of this theorem. For this we need the following definition.

**Definition 5.** Let $X$ be a manifold. A Kleinian group on $X$ is a discrete subgroup of diffeomorphisms $\Gamma$ acting properly discontinuously on some nonempty open set $\Omega \subset X$. We say that an open set $D \subset \Omega$ is a *fundamental domain* for the action of $\Gamma$ on $\Omega$ if $D$ does not contain two points of the same $\Gamma$-orbit and if moreover $\bigcup_{\gamma \in \Gamma} \gamma(D) = \Omega$.

**Notation.** For any subset $D$ of the manifold $X$, we call $\text{Ext}(D)$ the complement of $D$ in $X$. 
Theorem 5 (Klein). Let $\Gamma_i (i = 1, \ldots, m)$ a finite family of Kleinian groups on a compact connected manifold $X$. We suppose that each $\Gamma_i$ acts cocompactly on some open subset $\Omega_i$ of $X$ with fundamental domain $D_i$. We assume moreover that for each $i \neq j$, Ext($D_i$) ⊂ $D_j$, and that $D = \bigcap_{i=1}^{m} D_i \neq \emptyset$. Then we have:

(i) The group $\Gamma$ generated by the $\Gamma_i$’s is isomorphic to the free product $\Gamma_1 \ast \cdots \ast \Gamma_m$.

(ii) The group $\Gamma$ is Kleinian. More precisely, $\Omega = \bigcup_{\gamma \in \Gamma} \gamma(D)$ is an open subset of $X$, and $\Gamma$ acts properly discontinuously and cocompactly on $\Omega$, with fundamental domain $D$.

Proof. We do the proof for two groups $\Gamma_1$ and $\Gamma_2$, the final result being then obtained by induction. Let $\gamma = \gamma_s \gamma_{s-1} \cdots \gamma_2 \gamma_1$ be a word of $\Gamma$ such that $\gamma_i \in G_{j_i}$ ($j_i \in \{1, 2\}$ and $j_i \neq j_{i+1}$. Then the first condition on the fundamental domains yields the inclusions $\gamma_s \gamma_{s-1} \cdots \gamma_2 \gamma_1(D) \subset \gamma_s \gamma_{s-1} \cdots \gamma_2(Ext(\overline{D}_{j_2})) \subset \cdots \subset \gamma_s(Ext(\overline{D}_{j_{s-1}})) \subset Ext(\overline{D}_{j_s})$. So, for any nontrivial reduced $g$, $\gamma(D) \cap D = \emptyset$. This proves that $\gamma$ cannot be the identity, and (i) follows. In the same way, we prove that $\gamma(\overline{D}) \cap \overline{D} = \emptyset$ as soon as $s > 1$. Since $\overline{D}$ is compact in $\Omega_1$ and $\Omega_2$ and the action of $\Gamma_1$ and $\Gamma_2$ is proper, we get

Lemma 4. The intersection $\gamma(\overline{D}) \cap \overline{D}$ is empty for all but a finite number of $\gamma$’s.

Lemma 5. There is a finite family $\gamma_1, \ldots, \gamma_s$ of elements of $\Gamma$ such that $\overline{D} \cup \gamma_1(\overline{D}) \cup \cdots \cup \gamma_m(\overline{D})$ contains $\overline{D}$ in its interior.

Proof. We choose some open neighbourhood $U_1$ of $\partial D_1$ such that $U_1 \subset \Omega_1$ and $\overline{U}_1$ is a compact subset of $\Omega_1$. Since $D_1$ is a fundamental domain of $\Gamma_1$, for each $x \in U_1$ there exists a $\gamma_x \in \Gamma_1$ such that $x \in \gamma_x(\overline{D}_1)$. But since the action of $\Gamma_1$ is proper $\gamma(\overline{D}_1) \cap U_1$ is nonempty only for a finite number of elements $\gamma_1^{(1)}, \ldots, \gamma_s^{(1)}$ of $\Gamma_1$. Thus $\overline{D}_1 \cup U_1$ is included in $\overline{D}_1 \cup \gamma_1^{(1)}(\overline{D}_1) \cup \cdots \cup \gamma_s^{(1)}(\overline{D}_1)$, and $\overline{D}_1$ is contained in the interior of $\overline{D}_1 \cup \gamma_1^{(1)}(\overline{D}_1) \cup \cdots \cup \gamma_s^{(1)}(\overline{D}_1)$. But if $D'_1 = D_1 \setminus K$, where $K$ is a compact subset of $D_1$, then we also have $\overline{D}_1 \cup U_1 \subset \overline{D}_1 \cup \gamma_1^{(1)}(\overline{D}_1) \cup \cdots \cup \gamma_s^{(1)}(\overline{D}_1)$. In particular, when $K$ is the exterior of $D_2$, we get that $\overline{D} \cup U_1 \subset \overline{D} \cup \gamma_1^{(1)}(\overline{D}) \cup \cdots \cup \gamma_s^{(1)}(\overline{D})$.

Now we can apply the same argument for a neighbourhood $U_2$ of $\partial D_2$ in $\Omega_2$. We get a finite family $\gamma_1^{(2)}, \ldots, \gamma_s^{(2)}$ of $\Gamma_2$ such that $\overline{D} \cup U_2 \subset \overline{D} \cup \gamma_1^{(2)}(\overline{D}) \cup \cdots \cup \gamma_s^{(2)}(\overline{D})$. Setting $m = s + t$, $\gamma_i = \gamma_i^{(1)}$ for $i = 1, \ldots, s$ and $\gamma_{s+i} = \gamma_i^{(2)}$ for $i = 1, \ldots, t$, we get the lemma.

As a consequence of this lemma, we get that the set $\Omega = \bigcup_{\gamma \in \Gamma} \gamma(\overline{D})$ is open set.

It remains to prove that the action of $\Gamma$ on $\Omega$ is proper. Indeed, since $\Gamma$ is not a priori a convergence group, the fact that $\Gamma$ acts discontinuously on $\Omega$ no longer
ensures that the action is proper. That is why our assumptions (in particular the assumption of cocompactness) are stronger as for the classical Klein’s theorem on the sphere.

Suppose, on the contrary, that there is a sequence \((x_i)\) of \(\Omega\) converging to \(x_\infty \in \Omega\), and a sequence \((\gamma_i)\) tending to infinity in \(\Gamma\), such that \(y_i = \gamma_i(x_i)\) converges to \(y_\infty \in \Omega\). We can assume that \(x_\infty \in \overline{D}\). On the other hand, by definition of \(\Omega\), there is a \(\gamma_0\) such that \(y_\infty \in \gamma_0(D)\). Lemma 5 ensures that for \(i\) sufficiently large, \(x_i\) must be in \(\overline{D} \cup \gamma_1(D) \cup \cdots \cup \gamma_m(D)\), and \(y_i\) in \(\gamma_0(D) \cup \gamma_0 \gamma_1(D) \cup \cdots \cup \gamma_0 \gamma_m(D)\). But then, Lemma 4 implies that the sequence \((\gamma_i)\) takes its values in a finite set, a contradiction with the fact that \((\gamma_i)\) tends to infinity in \(\Gamma\).

We would like to apply the theorem above to combine Lorentzian Kleinian groups. Notice that for two Kleinian groups the condition \(\text{Ext}(D_1) \subset D_2\) implies \(\partial \Omega_1 \subset D_2\) and \(\partial \Omega_2 \subset D_1\). Together with Lemma 2, we get that if two cocompact Lorentzian Kleinian groups can be combined, then their fundamental domains have to contain a lightlike geodesic (in particular, no Kleinian group uniformizing a manifold with constant curvature can be combined with another Kleinian group). It turns out that this obstruction is the only one which forbids combining two Lorentzian Kleinian groups, as shown by Theorem 2, which we now prove.

6.1. Proof of Theorem 2. We choose \(\Delta_1 \subset D_1\) and \(\Delta_2 \subset D_2\), two lightlike geodesics. Since \(D_1\) and \(D_2\) are open, they contain not only one, but in fact infinitely many lightlike geodesics, so that we can moreover choose \(\Delta_1\) and \(\Delta_2\) disjoint. We begin with a useful lemma.

**Lemma 6.** Given \(\Delta_1\) and \(\Delta_2\) two disjoint lightlike geodesics of \(\text{Ei}_{n}\), there exists \(g \in \text{Conf}(\text{Ei}_{n})\) such that \((g^k)\) has mixed distortions and admits \(\Delta_1\) and \(\Delta_2\) as attracting and repelling circles.

**Proof.** The geodesic \(\Delta_1\) (resp. \(\Delta_2\)) is the projection on \(\text{Ei}_{n}\) of a 2-plane \((e_1', e_2')\) (resp. \((e_3', e_4')\)) of \(\mathbb{R}^{2,n}\). We choose moreover \(e_3'\) and \(e_4'\) such that \(q^{2,n}(e_1', e_3') = -2\) and \(q^{2,n}(e_2', e_4') = 2\). The \(q^{2,n}\)-orthogonal \(F\) to \((e_1', e_2', e_3', e_4')\) has Riemannian signature and we denote by \(e_5', \ldots, e_{n+2}'\) one of its orthonormal basis. Then we consider some element \(g\) of \(O(2, n)\), which writes in the base \((e_1', \ldots, e_{n+2}')\) as

\[
g = \begin{pmatrix}
e^\lambda & e\mu & e^{-\lambda} & e^{-\mu} \\
e^{-\lambda} & e^{\mu} & e^{-\mu} & 1 \\
e^{-\mu} & 1 & \cdots & 1
\end{pmatrix}
\]
If we choose $\lambda > \mu > 0$, then it is clear that $(g^k)$ has mixed distortions with $\Delta^+ = \Delta_1$ and $\Delta^- = \Delta_2$. 

We now take some $g \in \text{Conf}(\text{Ein}_n)$ as in the lemma above. Let us choose $V_1$ (resp. $V_2$) an open tubular neighbourhood of $\Delta_1$ (resp. $\Delta_2$) such that $\overline{V}_1 \subset D_1$ (resp. $\overline{V}_2 \subset D_2$). The complement of $V_i$ ($i = 1, 2$) in $\text{Ein}_n$ is denoted by $\text{Ext}(V_i)$. It follows from Proposition 5 (i) and (ii) that the set dynamically associated to $\text{Ext}(V_2)$ with respect to $(g^k)$ is included in $\Delta^+$. Since $\text{Ext}(V_2)$ contains a lightlike geodesic, it is exactly $\Delta^+$. Hence, for $k_0$ sufficiently large, $g^{k_0}(\text{Ext}(V_2)) \subset V_1$. We call $\Gamma'_2 = g^{k_0}\Gamma_2 g^{-k_0}$. The group $\Gamma'_2$ is a cocompact Lorentzian Kleinian group with fundamental domain $D'_2 = g^{k_0}(D_2)$. But $g^{k_0}(D_2)$ contains $g^{k_0}(\text{Int}(V_2))$, and as we just saw, $\text{Ext}(V_1) \subset g^{k_0}(\text{Int}(V_2))$. So $\text{Ext}(D'_2) \subset D_1$. We can then apply Theorem 5, and we get that the group generated by $\Gamma'_2$ and $\Gamma_1$ is still Kleinian, cocompact, and isomorphic to $\Gamma_1 \ast \Gamma'_2$, i.e. $\Gamma_1 \ast \Gamma_2$.

**Example 4.** All the cocompact Lorentzian Kleinian groups of the Examples 1 and 2 of Section 5 satisfy the hypothesis of Theorem 2. This is also the case of most instances of Example 3, when $\rho$ is injective with discrete image. Thus such groups can be combined and give new examples. Notice that in the proof of Theorem 2, the gluing element $g$ can be chosen in many ways. In particular, starting from two groups of the Examples 1, 2 or 3, suitable choices of $g$ will give combined groups which are Zariski dense in $O(2,n)$.

6.2. **Lorentzian surgery.** Theorem 2 reflects in fact the group theoretical aspect of a slightly more general process of conformal Lorentzian surgery.

Let $M_1$ and $M_2$ be two conformally flat Lorentzian manifolds (we do not make any compactness assumption). Suppose that $M_1$ contains a closed lightlike geodesic $\Delta_1$ admitting some open neighbourhood $U_1$ which embeds conformally, via a certain embedding $\phi_1$, into $\text{Ein}_n$. Suppose moreover that the same property is satisfied by $M_2$, for a closed lightlike geodesic $\Delta_2$, an open neighbourhood $U_2$, and a conformal embedding $\phi_2$. We can suppose that $\phi_1(\Delta_1)$ and $\phi_2(\Delta_2)$ are disjoint in $\text{Ein}_n$. By Lemma 6, $\phi_1(\Delta_1)$ and $\phi_2(\Delta_2)$ are the attracting and repelling circles of some element $g \in \text{Conf}(\text{Ein}_n)$. As in the proof of Theorem 2, there exist two open neighbourhoods $V_1$ and $V_2$ of $\Delta_1$ and $\Delta_2$ respectively, such that $V_1 \subset U_1$, $V_2 \subset U_2$, and $g(\text{Ext}(\phi_2(V_2))) = \phi_1(V_1)$. In particular $g(\partial(\phi_2(V_2))) = \partial(\phi_1(V_1))$ (recall that $\partial$ denotes the boundary). So the element $g$ provides a gluing map $f$ between $\partial V_1$ and $\partial V_2$. We denote by $\tilde{M}_1$ (resp. $\tilde{M}_2$) the manifold $M_1$ (resp. $M_2$) with $V_1$ (resp. $V_2$) removed. We call $M = \tilde{M}_1 \cup_f \tilde{M}_2$ the manifold obtained from $M_1 \cup M_2$ after identification of $\partial V_1$ and $\partial V_2$ by means of the map $f$. Since $g \in \text{Conf}(\text{Ein}_n)$, the “surgered manifold” $M$ is still endowed with a conformally flat Lorentzian structure. Theorem 2 ensures that if one starts with two compact Kleinian structures $M_1$ and $M_2$, the conformally flat structure on $\tilde{M}_1 \cup_f \tilde{M}_2$ is still Kleinian.
Remark 6. This surgery process is reminiscent of Kulkarni’s construction of a conformally flat Riemannian structure on the connected sum of two conformally flat Riemannian manifolds ([K1]). We do not know whether the connected sum of two conformally flat Lorentzian manifolds can still be endowed with a conformally flat Lorentzian structure.

7. Lorentzian Schottky groups

As an application of the former sections we study here the Lorentzian Schottky groups. These groups are interesting since we can completely determine their limit set and the Kleinian manifolds they uniformize. Moreover, they can be used to construct examples of conformally flat manifolds with some peculiar properties (see [Fr2]).

Let us consider a family \( \{(\Delta_1^-, \Delta_1^+), \ldots, (\Delta_g^-, \Delta_g^+)\} \) of pairs of lightlike geodesics in \( \text{Ein}_n \). We suppose moreover that the \( \Delta_i^\pm \) are all disjoint. By Lemma 6, there exists a family \( s_1, \ldots, s_g \) of elements of \( \text{Conf}(\text{Ein}_n) \) with mixed dynamics such that the attracting and repelling circles of \( s_i \) are precisely \( \Delta_i^+ \) and \( \Delta_i^- \). Looking if necessary at suitable powers \( s_i^k \) of \( s_i \), we can find open tubular neighbourhoods \( U_i^\pm \) of the \( \Delta_i^\pm \) with the following properties:

(i) The \( U_i^\pm \) are all disjoint.

(ii) \( s_i(\text{Ext}(U_i^-)) = U_i^+ \) for all \( i = 1, \ldots, g \).

Such a group \( \Gamma = \langle s_1, \ldots, s_g \rangle \) is called a Lorentzian Schottky group. Properties (i) and (ii) are classically known as ping-pong dynamics (see for example [dlH]). For each \( i \), the group \( \langle s_i \rangle \) acts properly cocompactly on the open set \( \text{Ein}_n \setminus (\Delta_i^- \cup \Delta_i^+) \), and a fundamental domain is just given by \( D_i = \text{Ein}_n \setminus (\overline{U_i^+} \cup \overline{U_i^-}) \). Now, since the \( \overline{U_i^\pm} \) are disjoint, we get that \( \text{Ext}(D_i) \subset D_j \) for all \( i \neq j \). If we call \( D = \bigcap_{i=1}^g D_i \), it is clear that \( D \neq \emptyset \). We then apply Theorem 5 to obtain

Proposition 8. A Lorentzian Schottky group \( \Gamma = \langle s_1, \ldots, s_g \rangle \) is a free group of \( \text{Conf}(\text{Ein}_n) \). Moreover, \( \Gamma \) is Kleinian, it acts properly and cocompactly on \( \Omega = \bigcup_{\gamma \in \Gamma} \gamma(D) \). A fundamental domain for this action is given by \( D = \bigcap_{i=1}^g D_i \).

We are now going to describe \( \Omega \) and its complement \( \Lambda \subset \text{Ein}_n \) more precisely.

Let us recall that in a finitely generated free group each element \( \gamma \) can be written in an unique way as a reduced word in the generators. We denote by \( |\gamma| \) the length of this word. Let us also recall that we can define the boundary \( \partial \Gamma \) of \( \Gamma \) as the set of totally reduced words of infinite length. Hence the elements of the boundary can be written as \( s_1^{e_1} \ldots s_g^{e_g} \ldots \) with \( e_j \in \{\pm 1\} \) and \( i_j e_j \neq -i_{j+1} e_{j+1} \) for all \( j \geq 1 \). Since we supposed that \( g \geq 2 \), the boundary \( \partial \Gamma \) is a compact metrizable space, homeomorphic to a Cantor set (see [GdlH]).
For each $k \in \mathbb{N}$, we call $F_k = \bigcup_{|\gamma| \leq k} \gamma(\overline{D})$, with the convention $F_0 = \overline{D}$. It is not difficult to check that $F_{k-1} \subset F_k$, and $\Omega = \bigcup_{k \in \mathbb{N}} F_k$. So, $\Lambda = \bigcap_{k \in \mathbb{N}} \text{Ext}(F_k)$.

For each $k$, we set $\Lambda_k = \text{Ext}(F_k)$, and thus, we also have $\Lambda = \bigcap_{k \in \mathbb{N}} \overline{\Lambda}_k$. The set $\overline{\Lambda}_k$ is a disjoint union of exactly $2g(2g-1)^k$ connected components, in one to one correspondence with the words of length $k + 1$ in $\Gamma$. For example, to the word $s_{i_1}^{1} \cdots s_{i_k}^{k+1}$ corresponds the component $s_{i_1}^{1} \cdots s_{i_k}^{k}(\overline{U_{i_{k+1}}}^{k+1})$ of $\overline{\Lambda}_k$. We can now state the following result.

**Lemma 7.** There is a homeomorphism $K$ between the boundary $\partial \Gamma$ and the space of connected components of $\Lambda$ (endowed with the Hausdorff topology for the compact subsets of $\text{Ein}_n$).

**Proof.** Let $\gamma_\infty = s_{i_1}^{1} \cdots s_{i_k}^{k+1} \cdots$ be an element of $\partial \Gamma$. We call $\gamma_k = s_{i_1}^{1} \cdots s_{i_k}^{k}$ and we look at the decreasing sequence of compact subsets $K(\gamma_k) = s_{i_1}^{1} \cdots s_{i_{k-1}}^{k-1}(\overline{U_{i_k}^{k}})$. This decreasing sequence of compact sets tends to a limit compact set $K(\gamma_\infty)$ for the Hausdorff topology. Since the $\overline{U_{i_k}^{k}}$ are connected, so are the $K(\gamma_k)$, and $K(\gamma_\infty)$ is itself connected. Let us remark that if $\gamma_\infty$ and $\gamma'_\infty$ are distinct in $\partial \Gamma$, then $K(\gamma_k)$ and $K(\gamma'_k)$ are disjoint for $k$ large (they represent two distinct components of $\overline{\Lambda}_k$), so that $K(\gamma_\infty)$ and $K(\gamma'_\infty)$ are disjoint.

Reciprocally, choose $x_\infty \in \Lambda$. Since $\Lambda = \bigcap_{k \in \mathbb{N}} \overline{\Lambda}_k$ with $\overline{\Lambda}_{k+1} \subset \overline{\Lambda}_k$, $x_\infty$ must be an element of some connected component $C_k \subset \overline{\Lambda}_k$ for each $k$. Moreover, $C_{k+1} \subset C_k$. But $C_k$ is then a decreasing sequence of compact subsets of the form $s_{i_1}^{1} \cdots s_{i_{k-1}}^{k-1}(\overline{U_{i_k}^{k}})$ and thus converges to a limit compact set $K(\gamma_\infty)$ for $\gamma_\infty = s_{i_1}^{1} \cdots s_{i_k}^{k} \cdots$.

We have proved that the mapping $K$ between $\partial \Gamma$ and the set of connected components of $\Lambda$ is a bijection. It remains to prove that it is a homeomorphism, and for this, it is sufficient to show that $K$ is continuous. Let us consider a sequence $\gamma_\infty^{(n)}$ of elements of $\Gamma$, converging to some $\gamma_\infty$. It means that there is a sequence $(r_n)$ of integers which tends to infinity, such that $\gamma_\infty^{(n)}$ and $\gamma_\infty$ have the same $r_n$ first letters. For each $n \in \mathbb{N}$, $K(\gamma_\infty^{(n)})$ is a decreasing sequence of compact sets $C_k^{(n)}$, where each $C_k^{(n)}$ is a connected component of $\overline{\Lambda}_k$. On the other hand, $K(\gamma_\infty)$ is the limit of a decreasing sequence of $C_k$, where each $C_k$ is a connected component of $\overline{\Lambda}_k$. Since $\gamma_\infty^{(n)}$ and $\gamma_\infty$ have the same $r_n$ first letters, we have $C_{r_{n-1}}^{(n)} = C_{r_{n-1}}$ for all $n$. Thus, the limit, as $n$ tends to infinity, of $C_{r_{n-1}}^{(n)}$ is $K(\gamma_\infty)$. But since $K(\gamma_\infty^{(n)}) \subset C_{r_{n-1}}^{(n)}$, we get that $\lim_{n \to \infty} K(\gamma_\infty^{(n)}) = K(\gamma_\infty)$ and we are done.

The next step is to show the following lemma.

**Lemma 8.** The connected components of $\Lambda$ are lightlike geodesics.
Proof. Let us consider $\gamma_\infty = s_1^{\varepsilon_1} \ldots s_k^{\varepsilon_k} \ldots$ in the boundary of $\Gamma$. We know that $K(\gamma_\infty)$ is the limit of the sequence $s_1^{\varepsilon_1} \ldots s_k^{\varepsilon_k} (\hat{U}_j^{\varepsilon_k})$. Since the sequence is decreasing, the limit remains the same if we consider a subsequence. Thus we can make the extra assumption that $K(\gamma_\infty)$ is the limit of a sequence $\gamma_k (\hat{U}_j^{\varepsilon_k})$, such that $(\gamma_k)$ tends simply to infinity and the first and last letters of $\gamma_k$ are always the same, namely $s_1^{\varepsilon_1}$ and $s_j^{\varepsilon_j}$. Observe that $j_1 \varepsilon_j \neq -j_0 \varepsilon_{j_0}$. We are going to discuss the different possible dynamics for $(\gamma_k)$, and we first prove that $(\gamma_k)$ cannot have bounded distortion.

Suppose that it is the case. We call $p^+$ (resp. $p^-$) and $C^+$ (resp. $C^-$) the attracting (resp. repelling) pole and cone of $(\gamma_k)$. If $x$ is a point of $D$, then for all $k \in \mathbb{N}$, $\gamma_k(x) \in U^{\varepsilon_1}_{i_1}$ and $\gamma_k^{-1}(x) \in U^{-\varepsilon_{j_1}}_{j_1}$. So we must have $p^+ \in U^{\varepsilon_1}_{i_1}$ and $p^- \in U^{-\varepsilon_{j_1}}_{j_1}$. In particular, $p^-$ is not in $U^{\varepsilon_0}_{j_0}$. On the other hand, it is a general fact that in Ein$_n$ any lightlike cone meets any lightlike geodesic (just because degenerate hyperplanes always meet null 2-planes in $\mathbb{R}^{2,n}$). In particular, the cone $C^-$ meets $\Delta^{\varepsilon_0}_{j_0}$ and thus $U^{\varepsilon_0}_{j_0}$. We call $V^{\varepsilon_0}_{j_0} = C^- \cap U^{\varepsilon_0}_{j_0}$. Since $U^{\varepsilon_0}_{j_0}$ does not contain $p^-$, we infer from Proposition 4 (i) and (ii) that $K(\gamma_\infty) = D(\gamma_k)(\hat{U}_j^{\varepsilon_k})$. More precisely, if $\hat{V}^{\varepsilon_0}_{j_0}$ is the set of lightlike geodesics of $C^-$ meeting $V^{\varepsilon_0}_{j_0}$, then $K(\gamma_\infty)$ is the closure of the union the lightlike geodesics of $\hat{\gamma}_\infty (\hat{V}^{\varepsilon_0}_{j_0})$ (see Proposition 4 for the notation $\hat{\gamma}_\infty$). In particular, $K(\gamma_\infty)$ contains a lightlike geodesic. Now some lightlike geodesic of $C^-$ does not meet $\hat{V}^{\varepsilon_0}_{j_0}$. Indeed, if this is not the case, then Proposition 4 (ii) ensures that $K(\gamma_\infty) = C^-$. But if we take $\gamma_\infty' \neq \gamma_\infty$, then $K(\gamma_\infty')$ contains some lightlike geodesic by the remark above. Since any lightlike geodesic meets $C^-$, we get a contradiction with the fact that $K(\gamma_\infty)$ and $K(\gamma_\infty)$ have to be disjoint.

Now let us perturb slightly the sets $U^{\varepsilon_0}_{j_0}$ and $U^{-\varepsilon_0}_{j_0}$ into some sets $U^{\varepsilon_0}_{j_0}$ and $U^{-\varepsilon_0}_{j_0}$, in order to get another fundamental domain $D'$, very close to $D$. Since it is very near to $D$, $\hat{D}'$ is included in some $F_k$ for $k$ sufficiently large, and so $\bigcup_{\gamma \in \Gamma} \gamma(D') = \bigcup_{\gamma \in \Gamma} \gamma(D)$. We prove as above that the limit of the compact sets $\gamma_k(U^{\varepsilon_0}_{j_0})$ is still a connected component of $\Lambda$ and consequently of the form $K(\gamma_\infty)$. We just saw that some lightlike geodesics of $C^-$ do not meet $\hat{V}^{\varepsilon_0}_{j_0}$, so that $\hat{V}^{\varepsilon_0}_{j_0}$ is not the whole of $S^{n-2}$. It is thus possible to choose $U^{\varepsilon_0}_{j_0}$ in such a way that some points of $\hat{V}^{\varepsilon_0}_{j_0}$ are not in $\hat{V}^{\varepsilon_0}_{j_0}$. But then $K(\gamma_\infty')$ and $K(\gamma_\infty)$ will be two different components, hence disjoint. On the other hand, since the intersection of $U^{\varepsilon_0}_{j_0}$ and $U'^{\varepsilon_0}_{j_0}$ is not empty ($\Delta^{\varepsilon_0}_{j_0}$ is inside), $K(\gamma_\infty)$ and $K(\gamma_\infty')$ must have some common points. We thus get a contradiction.

It remains to deal with the case where $(\gamma_k)$ has mixed or balanced distortions. Once again, if $x$ is a point of $D$ then for all $k \in \mathbb{N}$, $\gamma_k(x) \in U^{\varepsilon_1}_{i_1}$ and $\gamma_k^{-1}(x) \in U^{-\varepsilon_{j_1}}_{j_1}$. 

Hence the attracting circle $\Delta^+$ is in $U_{i_0}^{\pm}$ and the repelling one $\Delta^-$ is in $U_{j_0}^{\pm}$. In particular $\overline{U}_{j_0}^{\pm}$ does not meet $\Delta^-$. We infer from Proposition 3 and Proposition 5 that $\lim_{k \to \infty} \gamma_k(U_{i_0}^{\pm}) \subset \Delta^+$, but since $\overline{U}_{j_0}^{\pm}$ contains a lightlike geodesic, we have the equality $\lim_{k \to \infty} \gamma_k(U_{j_0}^{\pm}) = \Delta^+$. We finally obtain that $K(\gamma_\infty) = \Delta^+$. 

7.1. Proof of Theorem 3. We begin by proving that the group $\Gamma$ is of the first type. Suppose on the contrary that there is some sequence $(\gamma_k)$ in $\Gamma$ with bounded distortion. Then $D$ meets the repelling cone $C^-$. Otherwise $C^-$ would be included in some $U_1^{\pm}$, say $U_1^{+}$. But since $\Delta^-_1$ meets $C^-$, the intersection between $\Delta^-_1$ and $U_1^{+}$ would be nonempty, a contradiction. By Proposition 4 (ii), $\lim_{k \to \infty} \gamma_k(D)$ is a compact subset containing infinitely many lightlike geodesics. But $\lim_{k \to \infty} \gamma_k(D)$ is also a connected subset of $\Lambda$. This contradicts the fact that the connected components of $\Lambda$ are lightlike geodesics.

We claim that the equality $\Lambda_\Gamma = \Lambda$ holds. Indeed, for any sequence $(\gamma_k)$ of $\Gamma$ tending simply to infinity, $(\gamma_k)$ tends to $\Delta^+(\gamma_k)$. We thus see that $\Lambda_\Gamma \subset \Lambda$. Now it is a general fact that if a group $\Gamma$ acts properly cocompactly on some open set $\Omega$, then it cannot act properly on some open set $\Omega'$ strictly containing $\Omega$. So $\Omega$ cannot be strictly contained in $\text{Ein}_n \setminus \Lambda_\Gamma$, and we obtain $\Lambda_\Gamma = \Lambda$.

We now prove that $\Lambda_\Gamma$ is the product of $\mathbb{R}P^1$ with a Cantor set. The space $\text{Ein}_n$ is the quotient of $S^1 \times S^{n-1}$ by the product of antipodal maps, so that there is a fibration $f: \text{Ein}_n \to \mathbb{R}P^1$. The fibers of $f$ are conformal Riemannian spheres of codimension one. In the projective model they are obtained as the projection of the intersection between $C^{2,n}$ and some hyperplanes $P \subset \mathbb{R}^{2,n}$ of Lorentzian signature. As a consequence any lightlike geodesic is transverse to any fiber of $f$. Let us choose a fiber $\mathcal{F}_0$ above a point $j_0$ of $\mathbb{R}P^1$. From Lemmas 7 and 8, $\Lambda$ (and thus $\Lambda_\Gamma$) is transverse to $\mathcal{F}_0$ and intersects it along a Cantor set $\mathcal{C}$. For each $x \in \mathcal{C}$, we call $x(t)$ the unique element of $f^{-1}(t) \cap \Lambda_\Gamma$ such that $x$ and $x(t)$ are on the same lightlike geodesic of $\Lambda$. Then Lemma 7 ensures that the following mapping is a homeomorphism:

$$\mathbb{R}P^1 \times \mathcal{C} \to \Lambda,$$

$$(t, x) \mapsto x(t).$$

This proves (ii).

Due to the homeomorphism $K$ we get that, since the action of $\Gamma$ on its boundary is minimal (see for instance [GdlH]), the action of $\Gamma$ on the space of lightlike geodesics of $\Lambda_\Gamma$ is also minimal, which establishes (iii).

For the proof of (iv) we refer to Theorem 5 of [Fr2] (in fact, in [Fr2] we considered only particular cases of Schottky groups, but the proof of Theorem 5 includes the general case).
Acknowledgments. I would like to thank Thierry Barbot for his useful remarks on this text, the ACI “Structures géométriques et trous noirs”, as well as the referee, who made a lot of valuable suggestions to improve the original version. Thanks also go to the Institut für Mathematik of Humboldt University in Berlin, where part of this work was done in autumn 2003.
