Abstract. In 1997, Thomas Wolff proved sharp $L^3$ bounds for his circular maximal function, and in 1999, Kolasa and Wolff proved certain non-sharp $L^p$ inequalities for a broader class of maximal functions arising from curves of the form \{\(\Phi(x, \cdot) = r\)\}, where \(\Phi(x, y)\) satisfied Sogge’s cinematic curvature condition. Under the additional hypothesis that \(\Phi\) is algebraic, we obtain a sharp $L^3$ bound on the corresponding maximal function. Since the function \(\Phi(x, y) = |x - y|\) is algebraic and satisfies the cinematic curvature condition, our result generalizes Wolff’s $L^3$ bound. The algebraicity condition allows us to employ the techniques of vertical cell decompositions and random sampling, which have been extensively developed in the computational geometry literature.

1. Introduction

1.1. Background

Consider the Wolff circular maximal function

\[
M_\delta f(r) = \sup_x \frac{1}{|C^\delta(x, r)|} \int_{C^\delta(x, r)} |f|,
\]

where \(C^\delta(x, r)\) is the \(\delta\)-neighborhood of the circle centered at \(x\) of radius \(r\). In [13], Wolff proved that for each \(\epsilon > 0\) there exists a constant \(C_\epsilon\) such that

\[
\|M_\delta f\|_{L^3([1/2, 1])} \leq C_\epsilon \delta^\epsilon \|f\|_{L^3(\mathbb{R}^2)},
\]

which in particular implies that every BRK set (a planar set containing a circle of each radius \(r \in [1/2, 1]\)) must have Hausdorff dimension 2. It is not possible to omit the \(\delta^{-\epsilon}\) factor since if (1.2) held with this factor omitted, it would imply
that every BRK set had strictly positive Lebesgue measure, and this is known to be false. Wolff’s result built off of his earlier work\textsuperscript{1} (jointly with Kolasa) in [7], where he proved the bound

\begin{equation}
\|M^\delta f\|_q \leq C_{p,q} \delta^{\frac{1}{2} \left(\frac{1}{p'} - 1\right)} \|f\|_p, \quad p < \frac{8}{3}, \quad q \leq 2p'.
\end{equation}

Equation (1.3) can almost be obtained by interpolating (1.2) with the trivial bound

\begin{equation}
\|M^\delta f\|_\infty \leq C\delta^{-1} \|f\|_1,
\end{equation}

though in doing so we pick up an additional $C_\epsilon \delta^\epsilon$ factor.

However, this earlier Kolasa–Wolff result applied not only to circles but to any family of curves satisfying Sogge’s cinematic curvature condition first introduced in [12]; let $U$ be a neighborhood of $(a, b) \in \mathbb{R}^2 \times \mathbb{R}^2$ and $\Phi: U \to \mathbb{R}$ with $\Phi$ smooth. Then the family of curves\textsuperscript{2} $\mathcal{F}(x, r) = \{y: \Phi(x, y) = r\}$ is said to satisfy the cinematic curvature condition provided

\begin{equation}
\nabla_y \Phi(a, b) \neq 0
\end{equation}

and

\begin{equation}
det \left( \nabla_x \begin{bmatrix}
eq 0 
\nabla_y \Phi(x, y) 
\nabla_y \left( \frac{\nabla_x \Phi(x, y)}{\nabla_y \Phi(x, y)} \right) 
\end{bmatrix} \right)_{(x, y) = (a, b)} \neq 0,
\end{equation}

where $e$ is a unit vector orthogonal to $\nabla_y \Phi(a, b)$. While there are two potential choices of vector $e$, the two choices only differ by a sign, so the veracity of (1.6) is independent of the choice made.

Informally, the second condition is a quantitative version of the statement that two distinct curves cannot be tangent to second order—it guarantees that if two curves $\mathcal{F}$ and $\mathcal{F}'$ intersect at a point $x$, then their normal vectors at $x$ or their curvature at $x$ (or both) must differ by at least the distance between $\mathcal{F}$ and $\mathcal{F}'$ in some suitable metric.

Let $\mathcal{F}_\delta(x, r)$ be the $\delta$-neighborhood of $\mathcal{F}$. Define

\begin{equation}
M^\delta_{\mathcal{F}} f(r) = \sup_{x \in U_1} \frac{1}{|\mathcal{F}_\delta(x, r)|} \int_{\mathcal{F}_\delta(x, r)} |f|,
\end{equation}

where $U_1$ is a sufficiently small neighborhood of $a$. Then Kolasa and Wolff proved that for any $f$ supported in a sufficiently small neighborhood of $b$,

\begin{equation}
\|M^\delta_{\mathcal{F}} f\|_{L^p([1/2, 1])} \leq C_{p,q} \delta^{\frac{1}{2} \left(\frac{1}{p'} - 1\right)} \|f\|_p, \quad p < \frac{8}{3}, \quad q \leq 2p'.
\end{equation}

\textsuperscript{1}While [7] was published after [13], [7] was written first.

\textsuperscript{2}Note that we are reversing the role of $x$ and $y$ from the notation of [7].
1.2. New results

Theorem 1.1. Let $\Phi$ be an algebraic function satisfying the cinematic curvature conditions (1.5) and (1.6) at $(a, b)$ and let $U_1$ be a sufficiently small neighborhood of $a$. Then for all $f$ supported in a sufficiently small neighborhood of $b$ and for all $\epsilon > 0$, there exist a constant $C_\epsilon$ depending only on $\epsilon$ and $\Phi$ such that for all $\delta > 0$,

$$\|M_\delta^\epsilon f\|_{L^3([1/2,1])} \leq C_\epsilon \delta^\epsilon \|f\|_{L^3(\mathbb{Z})}. \quad (1.9)$$

Remark 1.2. See Appendix B for the definition of an algebraic function and related concepts.

Remark 1.3. Theorem 1.1 generalizes (1.2). Indeed, $\Phi(x,y) = |x-y|$ is clearly algebraic, and by the rotational, translational, and scale invariance of $\Phi$, in order to verify the cinematic curvature condition it suffices to verify the condition at the point $a = (0,0)$, $b = (1,0)$. Then $e = (0,1)$ and the determinant in (1.6) is 1. Furthermore, if

$$\Phi(x,y) = |x-y| + P(x,y) \quad (1.10)$$

for $P$ a smooth algebraic function with $\|P\|_{C^2}$ sufficiently small, then $\Phi$ satisfies (1.6) uniformly in the choice of $a, b \in [0,1]^2$. Thus we obtain (1.9) for any family of smooth algebraically perturbed circles, provided the perturbation is not too large.

We shall prove Theorem 1.1 by modifying Schlag’s arguments in [10]. These arguments rely on a key incidence lemma for circles, which is proved by Wolff in [15]. This incidence lemma employs various bounds on the behavior of circle intersections, which do not obviously hold for the more general class of curves we are considering. Luckily, most of the analogous statements were proved by Kolasa and Wolff in [7], so Theorem 1.1 can largely be obtained by patching together previously known results.

The constraint that $\Phi$ be algebraic is quite restrictive and is likely not optimal (indeed it is reasonable to conjecture that it is completely unnecessary). However, this constraint allows us to use a “semi-cylindrical algebraic decomposition” argument from real algebraic geometry. We shall discuss in Section 6 some conjectures about how the algebraic requirements can be weakened.

1.3. Proof sketch

Through standard reductions, it suffices to prove a discretized version of a bound on the adjoint of the maximal operator $M_\delta^\epsilon$. Roughly speaking, if we have a collection of “tubes” $\{\Gamma^\delta\}$ corresponding to curves with $\delta$-separated radii (see (2.1) below for the definition of $\Gamma$), we need to control the area of the region where many of these tubes overlap. This is Lemma 2.1 below.

In [10], Schlag showed that (1.9) holds for families of curves satisfying two conditions. The first is a bound (2.9) below on $|\Gamma^\delta \cap \tilde{\Gamma}^\delta|$ (where here $|\cdot|$ denotes Lebesgue measure) provided we have control over how close $\Gamma$ and $\tilde{\Gamma}$ are
to each other in a suitable parameter space and how close the two curves are to being tangent.

The second requirement, which is made precise in (2.10) below, controls the number of almost tangencies that can occur between the elements of $\mathcal{W}$ and $\mathcal{B}$ if $(\mathcal{W}, \mathcal{B})$ is a $t$-bipartite pair. Informally, two collections of curves $\mathcal{W}$ and $\mathcal{B}$ are called a $t$-bipartite pair if every two curves in $\mathcal{W}$ (resp $\mathcal{B}$) are close in an appropriate parameter space while those in $\mathcal{W}$ are far from those in $\mathcal{B}$ (there are some additional technical requirements that we shall gloss over here. The full details can be found in Definition 2.3). The requirement is a quantitative analog of the incidence geometry result that $N$ circles in $\mathbb{R}^2$ can have at most $C_\epsilon N^{3/2 + \epsilon}$ tangencies between pairs of circles. The incidence geometry result was proved in [5], and in [15], Wolff obtained the quantitative analog that was then used in Schlag’s argument.

The bulk of this paper will be devoted to showing that families of curves arising from algebraic defining functions $\Phi$ satisfy the second requirement, i.e., that (2.10) is true. Once this has been established, one can run Schlag’s arguments virtually verbatim to obtain Theorem 1.1.

2. Definitions and initial reductions

First, let us assume $U = U_1 \times U_2$, with $U_1$ and $U_2$ sufficiently small disks centered at $a$ and $b$ respectively (the requirement that $U_1$ and $U_2$ be disks will be relevant—we need $U_2$ to be a semi-algebraic set). In particular, by selecting $U_1, U_2$ sufficiently small we can assume that the cinematic curvature conditions hold for every point $(x, y) \in U_1 \times U_2$ with uniform bounds on $\nabla_y \Phi$ and with the determinant in (1.6) bounded uniformly away from 0.

Throughout this paper, $C, C'$, etc. will denote constants that are allowed to vary from line to line. We will say $X \lesssim Y$ or $X$ is $O(Y)$ if $X < CY$ and $X \sim Y$ if $X \lesssim Y$ and $Y \lesssim X$.

Fix $0 < \alpha < C^{-1} \text{diam}(U_2)$. For $x \in U_1, r \in [1/2, 1]$, we define

(2.1) $\Gamma(x_0, r_0) = \{y \in B(b, \alpha) : \Phi(x_0, y) = r_0\}.$

We shall call these sets $\Phi$-circles, and if $\Gamma$ is a $\Phi$-circle then $\Gamma^\delta$ will denote its $\delta$-neighborhood. If $\Gamma, \Gamma'$, etc. are $\Phi$-circles, then unless otherwise noted, $x_0, r_0$ and $\tilde{x}_0, \tilde{r}_0$ will refer to their respective centers and radii. The $\Phi$-circles defined here are strict subsets of the sets $\mathcal{F}$ defined in the introduction. However, if the function $f$ is supported on a sufficiently small neighborhood of $b$ then we can define a maximal function analogous to (1.7) with $\Gamma$ in place of $\mathcal{F}$, and the two maximal functions will agree. Thus we shall henceforth work with curves $\Gamma$ defined by (2.1).

We shall restrict our attention to those $\Phi$-circles $\Gamma$ with $x_0 \in U_1$ and $r_0 \in (1 - \tau, 1)$ for $\tau$ a sufficiently small constant which depends only on $\Phi$. By standard compactness arguments, we can recover $L^p([1/2, 1])$ bounds on $M_\Phi$ from those on the “restricted” version of $M_\Phi$ by considering the supremum over a finite number of scaled versions of the function.
Using standard reductions (see e.g. [10]), in order to prove Theorem 1.1 it suffices to prove the following estimate:

**Lemma 2.1.** For $\eta > 0$ and $\delta$ sufficiently small depending on $\eta$, let $\mathcal{A}$ be a collection of $\Phi$-circles with $\delta$-separated radii, with each radius lying in $(1-\tau,1)$. Then there exists $\tilde{\mathcal{A}} \subset \mathcal{A}$ such that for all $\Gamma \in \tilde{\mathcal{A}}$ and $\delta < \lambda < 1$,

$$\left| B(b, C^{-1}\alpha) \cap \{ y \in \Gamma^\delta : \sum_{\Gamma \in \mathcal{A}} \chi_{\tilde{\Gamma}}(y) > \delta^{-\eta} \lambda^{-2} \} \right| \leq \lambda |\Gamma^\delta|.$$  

In [10], Schlag took Wolff’s combinatorial incidence result from [15] and used it in conjunction with an induction on scales argument to prove the analogue of Lemma 2.1 (in [10], this is Lemma 8). In order to state Schlag’s theorem, we first need some additional definitions.

**Definition 2.2.** For $X \subset B(b,\alpha)$, we define

$$\Delta_X(\Gamma, \tilde{\Gamma}) = \inf_{\gamma \in X : \Phi(x_0, y) = r_0} |y - \tilde{y}| + \frac{|\nabla_y \Phi(x_0, y)|}{\|\nabla_y \Phi(x_0, y)\|} |\nabla_y \Phi(x_0, \tilde{y}) - \nabla_y \Phi(\tilde{x}_0, \tilde{y})|.$$  

Crucially,

$$\Delta_{B(b, C^{-1}\alpha)}(\Gamma, \tilde{\Gamma}) \geq \Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}),$$

but there exists a finite family of translates $\{t_i\} \subset \mathbb{R}^2$ (the cardinality of the family depends only on $C$) so that

$$\inf_{i} \Delta_{B(b+t_i, C^{-1}\alpha)}(\Gamma, \tilde{\Gamma}) \leq \Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}).$$

In the example $\Phi(x, y) = |x - y|$, $\Delta_X(\Gamma, \tilde{\Gamma})$ describes how “far” (in $(x_0, r_0)$ parameter space) we would need to move $\Gamma$ so that $\tilde{\Gamma}$ and the newly moved curve $\Gamma'$ are incident at some point in $X$. Indeed, if $\Phi(x, y) = |x - y|$ and $X = \mathbb{R}^2$ then $\Delta_X(\Gamma, \tilde{\Gamma}) = ||x_0 - \tilde{x}_0| - |r_0 - \tilde{r}_0||$, provided $x_0, \tilde{x}_0 \in U_1$ with diam$(U_1)$ sufficiently small so that in particular, the only way circles can be tangent is if they are internally tangent.

Let

$$d(\Gamma, \tilde{\Gamma}) = |x_0 - \tilde{x}_0| + |r_0 - \tilde{r}_0|.$$  

This $d(\cdot, \cdot)$ is a metric on the space of curves. Throughout our arguments, the particular choice of metric will not be important since we will not care about multiplicative constants.

**Definition 2.3.** Let $\mathcal{W}, \mathcal{B}$ be collections of $\Phi$-circles. We say that $(\mathcal{W}, \mathcal{B})$ is a $t$-bipartite pair if

$$|r_0 - \tilde{r}_0| \geq \delta \quad \text{for all } \Gamma, \tilde{\Gamma} \in \mathcal{W} \cup \mathcal{B},$$

$$d(\Gamma, \tilde{\Gamma}) \in (t, 2t) \quad \text{if } \Gamma \in \mathcal{W}, \tilde{\Gamma} \in \mathcal{B},$$

$$d(\Gamma, \tilde{\Gamma}) \in (0, t) \quad \text{if } \Gamma, \tilde{\Gamma} \in \mathcal{W} \text{ or } \Gamma, \tilde{\Gamma} \in \mathcal{B}.$$
Definition 2.4. A $(\delta, t)$-rectangle $R$ is the $\delta$-neighborhood of an arc of length $\sqrt{\delta/t}$ of a $\Phi$-circle $\Gamma$. We say that a $\Phi$-circle $\Gamma$ is incident to $R$ if $R$ is contained in the $C_1 \delta$ neighborhood of $\Gamma$. We say that $R$ is of type $(\gtrsim \mu, \gtrsim \nu)$ relative to a $t$-bipartite pair $(W, B)$ if $R$ is incident to at least $C \mu$ curves in $W$ and at least $C \nu$ curves in $B$ for some absolute constant $C$ to be specified later.

We are now able to state Schlag’s result.

Proposition 2.5 (Schlag). Let $A$ be a family of $\Phi$-circles with $\delta$-separated radii that satisfy the following requirements:

(i) $\left| \Gamma^\delta \cap \tilde{\Gamma}^\delta \cap B(b', C^{-1} \alpha) \right| \lesssim \frac{\delta^2}{(d(\Gamma, \tilde{\Gamma}) + \delta)^{1/2}(\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) + \delta)^{1/2}}$ for any $b'$ in a sufficiently small neighborhood of $b$.

(ii) For any $t$-bipartite pair $(W, B)$, with $t > C \delta$ for an appropriate choice of $C$; $W, B \subset A$; $\#W = m; \#B = n$; and for any $\epsilon > 0$, the number of $(\gtrsim \mu, \gtrsim \nu)$ $(t, \delta)$-rectangles is at most

$$C_\epsilon (mn)^\epsilon \left( \frac{m n}{\mu \nu} \right)^{3/4} + \frac{m}{\mu} + \frac{n}{\nu}.$$ 

Then Lemma 2.1 holds for the collection $A$.

Proof. The proof of this theorem can be found in Section 4 of [10]. However, we need the following minor modifications.

• Schlag actually requires the bound

$$\left| \Gamma^\delta \cap \tilde{\Gamma}^\delta \right| \lesssim \frac{\delta^2}{(d(\Gamma, \tilde{\Gamma}) + \delta)^{1/2}(\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) + \delta)^{1/2}}.$$ 

in place of (2.9). However, (2.11) can be obtained from (2.9) by summing over finitely many translates of the ball $B(b, C^{-1} \alpha)$.

• Schlag stipulates that requirement (ii) in the above theorem hold for all values of $t$ and $\delta$, not merely those for which $t > C \delta$. However, there are at most $\lesssim \delta^{-2} (\delta, t)$-rectangles incident to $(W, B)$, and if $t < C \delta$ we can use this fact in place of the bound from (2.10).

The next sections shall be devoted to proving that any $\delta$-separated family of $\Phi$-circles satisfy the two requirements from Proposition 2.5. Once this has been established we will have proved Theorem 1.1. The first requirement will not present much difficulty; indeed, it was already proved by Kolasa and Wolff in [7], and it is Property 4.7 in Section 4 below. Thus the bulk of our efforts will be devoted to proving that the second requirement is satisfied. This will appear as Lemma 5.18 in Section 5.
3. Algebraic considerations

Let $\Gamma = \Gamma(x_0, r_0)$ be a $\Phi$-circle and $X \subset B(b, \alpha)$ an open semi-algebraic set of dimension 2 (see Appendix B for the definition of the dimension of a semi-algebraic set); in our discussion below we will only consider balls. For $w = (w_1, w_2, w_3) \in \mathbb{R}^3$, let

$$V_{\Gamma, X, w} = \{(x, r, y) \in U_1 \times (1 - \tau, 1) \times X : \Phi(x_0, y) - r_0 = w_1, \Phi(x, y) - r = w_2, \nabla_y \Phi(x_0, y) \wedge \nabla_y \Phi(x, y) = w_3\},$$

(3.1)

where

$$(z^{(1)}, z^{(2)}) \wedge (z^{(1)}, z^{(2)}) = z^{(1)}z^{(2)} - z^{(2)}z^{(1)}.$$

This $V_{\Gamma, X, w}$ should be thought of as the space of pairs $(\tilde{\Gamma}, y)$ with $\tilde{\Gamma}$ a $\Phi$-circle tangent to $\Gamma$ at the point $y \in X$. Intuitively, we can think of $w_1, w_2, w_3$ as being 0. However, setting $w_1, w_2, w_3$ equal to 0 might cause $V_{\Gamma, X, w}$ to fail to have the correct dimension. Thus we shall choose a very small “generic” choice of $w_1, w_2, w_3$ which fixes this problem. This will be elaborated upon in Lemma 3.1.

Let

$$S_{\Gamma, X, w} = \pi(x, r)V_{\Gamma, X, w} \cap \{(x, r) : |x - x_0| > C\delta\},$$

(3.2)

for an appropriately chosen $C$, where $\pi(x, r): (x, r, y) \mapsto (x, r)$ is the projection operator. $S_{\Gamma, X, w}$ should be thought of as the set of $\tilde{\Gamma}$ that are incident to $\Gamma$ at some point $y \in X$. In the example where $\Phi(x, y) = |x - y|$, $S_{\Gamma, X, 0}$ is a section of the right-angled “light cone” with vertex $(x_0, r_0) \in \mathbb{R}^3$, i.e.,

$$S_{\Gamma, X, 0} \subset \{(x, r) : |x - x_0| = |r - r_0|\}.$$

**Lemma 3.1.** For an appropriate choice of $0 \leq w_1, w_2, w_3 < C^{-1}\delta$, $S_{\Gamma, X}$ is a semi-algebraic set of bounded complexity. Furthermore, if $X = B(b, \alpha)$ then $S_{\Gamma, X}$ has (semi-algebraic) dimension 2.

**Proof.** We shall first show that if $w_1, w_2, w_3$ are chosen appropriately then $V_{\Gamma, X, w}$ is a semi-algebraic set of codimension 3. It suffices to show that the the defining functions in (3.1) are algebraic functions whose zero-sets intersect transversely. $\Phi(x_0, y) - r_0$ and $\Phi(x, y) - r$ are immediately seen to be smooth and algebraic since $\Phi$ is smooth and algebraic. The components of $\nabla_y \Phi(x_0, y)$ and $\nabla_y \Phi(x, y)$ are smooth and algebraic since the partial derivatives of a smooth algebraic function are smooth and algebraic, and thus $\nabla_y \Phi(x_0, y) \wedge \nabla_y \Phi(x, y)$ is smooth and algebraic. The complexity of these functions is clearly independent of the choice of $\Gamma$. Finally, by Sard’s theorem we can find $0 \leq w_1, w_2, w_3 < C^{-1}\delta$ such that $(w_1, w_2, w_3)$ is a regular value of the map

$$(x, r, y) \mapsto (\Phi(x_0, y) - r_0, \Phi(x, y) - r, \nabla_y \Phi(x_0, y) \wedge \nabla_y \Phi(x, y)).$$

For such a choice of values of $w_1, w_2, w_3$ we have that $S_{\Gamma, X, w}$ has geometric codimension 3, and thus semi-algebraic codimension 3, as desired (see Appendix B for a review of the relevant real algebraic geometry).
By the Tarski–Seidenberg theorem, \( \pi(x, r)V_{\Gamma, X, w} \) is semi-algebraic of bounded complexity, and thus so is \( S_{\Gamma, X, w} \). At this point, the dimension of the components of \( S_{\Gamma, X, w} \) could be 0, 1, or 2. However, we shall show in Corollary 4.10 below that if \( X = B(b, \alpha) \), then \( S_{\Gamma, X, w} \) is a smooth manifold of dimension 2 or 3, and thus the components of \( S_{\Gamma, X} \) are in fact of (semi-algebraic) dimension 2.

\[ \text{Remark 3.2.} \] It is somewhat curious to note that in our proof, we use algebraic considerations to show \( \dim(S_{\Gamma, X, w}) \leq 2 \) and differential geometric considerations to show \( \dim(S_{\Gamma, X, w}) \geq 2 \), and thus conclude that \( \dim(S_{\Gamma, X, w}) = 2 \).

\[ \text{Definition 3.3.} \] Abusing notation slightly, we shall suppress the dependence of \( S_{\Gamma, X, w} \) on \( w \), and we shall define \( S_{\Gamma, X} \) to be \( S_{\Gamma, X, w} \) for an appropriate choice of \( w \), the existence of which is guaranteed by Lemma 3.1. None of our arguments below will depend on the specific choice of \( w \), and all of the constants in the estimates below will be independent of the choice of \( w \), provided \( |w| < C^{-1}\delta \) for a sufficiently large constant \( C \).

We have defined \( S_{\Gamma, X} \) and \( \Delta_X \) so that

\[ S_{\Gamma, X, 0} = \{ \Gamma': \Delta_X(\Gamma, \Gamma') = 0 \}, \]

and thus since \( 0 \leq w_1, w_2, w_3 \leq C^{-1}\delta \),

\[ S_{\Gamma, X} \in \{ \Gamma': \Delta_X(\Gamma, \Gamma') = 0 \} + B(0, C^{-1}\delta), \]

\[ \{ \Gamma': \Delta_X(\Gamma, \Gamma') = 0 \} \in S_{\Gamma, X} + B(0, C^{-1}\delta), \]

where the + symbol denotes the Minkowski sum. These inclusions are the key facts linking the algebraic and geometric properties of \( \Phi \). Lemma 3.1 allows us to use the technique of semi-cylindrical algebraic decompositions (also known as vertical algebraic decompositions) to decompose \( \mathbb{R}^3 \) into a collection of “cells” adapted to a collection of surfaces \( \{ S_{\Gamma, X} \} \). Informally, a cell is an open subset of \( \mathbb{R}^3 \) whose boundary consists of pieces of the surfaces from the collection \( \{ S_{\Gamma, X} \} \) as well as additional surfaces that are added to guarantee that the cells have certain favorable properties. More precisely we have the following result:

\[ \text{Lemma 3.4.} \] Let \( \mathcal{D} \) be a collection of \( \Phi \)-circles, \( \#\mathcal{D} = N \). Then there exists an algorithm for creating a vertical decomposition of \( U_1 \times (1 - \tau, 1) \) (recall that \( U_1 \) and \( \tau \) were specified in Section 2 and depend only on \( \Phi \)) into \( \lesssim N^3 \log N \) open (in \( \mathbb{R}^3 \)) cells \( \{ \Omega_i \} \) such that \( U_1 \times (1 - \tau, 1) \) is the union of sets of the following types:

- cells,
- the dividing surfaces \( \{ S_{\Gamma, B(b, \alpha)} : \Gamma \in \mathcal{D} \} \),
- vertical walls: 2-dimensional semi-algebraic sets whose projections under the map \( \pi_x : (x, r) \mapsto x \) are 1-dimensional semi-algebraic sets.

The cells in this decomposition have the property that

\[ \Omega \cap S_{\Gamma, B(b, \alpha)} = \emptyset \text{ for all cells } \Omega \text{ and all } \Gamma \in \mathcal{D}. \]
Estimates for a variable coefficient Wolff maximal function

Furthermore, for each cell $\Omega$ in the decomposition, there is a bounded number (6 will suffice) of dividing surfaces such that $\Omega$ is one of the cells arising from the decomposition algorithm applied to this subcollection of surfaces (i.e. the existence of the other $N-6$ surfaces is irrelevant if all we care about is the cell $\Omega$).

Proof. This statement follows from the techniques developed by Chazelle, Edelsbrunner, Guibas, and Sharir in [4]. Unfortunately, while Theorem 3.4 is claimed in [4] and follows (with some effort) from the methods described in Chapter 8 of [1], we are unaware of a complete and detailed proof of Theorem 3.4 in the literature. The author intends to present such a proof in his forthcoming PhD thesis. In the interests of keeping this paper self contained, we will give a brief expository sketch of the vertical algebraic decomposition in Appendix A.

Lemma 3.5. Let $B$ be a collection of $\Phi$-circles, $\#B = n$. Randomly select (see Remark 3.6) a subset $D \subset B$ with $\#D = N < C^{-1}n$, and let $\{\Omega_i\}_{i=1}^M$, $M \leq N^3 \log N$ be the cells from Lemma 3.4. Then with high probability (see Remark 3.7) we have that for each $i$,

\[ \# \{ \Gamma \in B : S_{\Gamma, B(b, \alpha)} \cap \Omega_i \neq \emptyset \} \lesssim \frac{N \log n}{n}. \]

Remark 3.6. To obtain our random selection we shall take a uniformly distributed random sample with replacement from $B$. However, our algorithm will only work if the elements of the sample are all distinct. By requiring that $N \leq \frac{1}{C}n$ for $C$ sufficiently large, we can ensure that this will occur with high probability, so this assumption will not cause difficulty.

Remark 3.7. By “high probability” we mean that for any probability $P < 1$ we can select a choice of constant $C$ in the quasi-inequality in (3.7) so that the decomposition satisfies (3.7) with probability at least $P$. Later in the proof of Theorem 1.1 we shall need the above decomposition to satisfy additional properties which also occur with high probability (relative to another set of constants that we can weaken at will). We can ensure that all of these properties are simultaneously satisfied by requiring that each of the properties are separately satisfied with sufficiently high probability and using the trivial union bound.

Proof. Lemma 3.5 follows from Lemma 3.4 by the technique of random sampling (see e.g. [5]). Again, we shall briefly review this technique in Appendix A.

Lemma 3.4 (which is only used to prove Lemma 3.5) is the only place where Lemma 3.1 is used, and it is thus the only place where we use the requirement that $\Phi$ be algebraic. We shall discuss in Section 6 some conjectures about how to obtain Lemma 3.4 through other (less algebraic) means, though our best attempts in this direction have thus far yielded only provisional results.

Added 2/14/2012: In a recent paper, the author has obtained an analogue of Lemma 3.5 using the discrete polynomial ham sandwich theorem of Guth and Katz in place of Lemma 3.4. With this new technique, the requirement that $\Phi$ be algebraic is no longer necessary, i.e. Theorem 1.1 is established for all defining functions $\Phi$ satisfying the cinematic curvature condition. See [16] for further details.
4. Cinematic curvature and its implications

Many of Wolff’s arguments from [13] rely on the local differential properties of families of circles. The relevant properties are captured by the notion of cinematic curvature defined in the introduction. In [7], Kolasa and Wolff establish several key properties of families of curves with cinematic curvature which we shall recall below.

Property 4.1 (Straightening out). Let \( x_0 \in U_1 \). Then we can find a diffeomorphism \( \psi_{x_0} : U_2' \to U_2 \) and a choice of \( r_0 = r_0(x_0) \) such that
\[
\Phi(x_0, \psi_{x_0}(y)) - r_0 = y^{(2)},
\]
where \( U_2' \) is an appropriately chosen domain (which may no longer be a disk).

Furthermore for fixed \( y_0 \),
\[
\psi_{x_0}(y_0) \text{ and } r_0(x_0) \text{ are continuous functions of } x_0.
\]

This is discussed on page 126 of [7]. To simplify notation, we shall say that \( \Phi \) has been straightened out around \( x_0 \) if we (temporarily) replace the function \( \Phi(x_0, \cdot) \) with \( \Phi(x_0, \psi_{x_0}(\cdot)) - r_0(x_0) \), i.e., in “straightened out” coordinates, \( \Phi(x_0, y) = y^{(2)} \).

Note that if we straighten out around \( x_0 \) then in this new coordinate system \( \Phi \) might no longer be algebraic. This will not pose any problems to our analysis below; we shall only be straightening out to simplify the proofs of certain diffeomorphism-invariant statements, and the statement can then be “pulled back” to the original (semi-algebraic) \( \Phi \). This process may change some of the constants involved in the relevant statements. However (4.1) will guarantee that the constants are worsened by at most a bounded amount so we can safely ignore this problem.

Property 4.2 (Derivative bounds). If we straighten out \( \Phi \) at \( x_0 \), then for \( y \in B(0, \alpha) \),
\[
|\partial_{y_1} \Phi(x, y)| + |\partial_{y_1^2} \Phi(x, y)| \sim |x - x_0|,
\]
\[
|\partial_{y_0} \Phi(x, \psi_{x_0}(y))| \sim 1,
\]
where \( \partial_{y_1} \) denotes the partial derivative in the \( y_1 \)-direction, etc. The constants in the quasi-equalities above are uniform in all variables. Indeed, since the cinematic curvature condition is diffeomorphism invariant, (4.2) and (4.3) are equivalent to the cinematic curvature condition. This is addressed in equation (21) of [7] and the surrounding discussion.

Property 4.3 (Unique point of parallel normals). Let \( \Gamma, \tilde{\Gamma} \) be \( \Phi \)-circles with
\[
\Delta_{B(0, C^{-1} \alpha)}(\Gamma, \tilde{\Gamma}) \leq C^{-1} |x_0 - \tilde{x}_0|
\]
for a sufficiently large constant \( C' \). Then there is a unique point
\[
\xi = \xi(x_0, r_0, \bar{x}_0) \in \Gamma \cap B(0, \alpha)
\]
such that

\[(4.4) \quad \nabla_y \Phi(x_0, \xi) \wedge \nabla_y \Phi(\bar{x}_0, \xi) = 0.\]

Furthermore,

\[(4.5) \quad |\Phi(\bar{x}_0, \xi) - \bar{r}_0| \lesssim \Delta_{B(b, C^{-1}\alpha)}(\Gamma, \bar{\Gamma}),\]

and

\[(4.6) \quad \Gamma \cap \bar{\Gamma} \cap B(b, C^{-2}\alpha) \subset B\left(\xi, C\left(\frac{\Delta_{B(b, C^{-1}\alpha)}(\Gamma, \bar{\Gamma})}{|x_0 - \bar{x}_0|}\right)^{1/2}\right).\]

Equations (4.5) and (4.6) are equations (26) and (27) in [7].

**Property 4.4** (Appolonius-type bounds). Let \(t > C\delta\). Fix three \(\Phi\)-circles \(\Gamma_1, \Gamma_2,\) and \(\Gamma_3\), let \(B_0 = B(b, C^{-2}\alpha)\), and let

\[
\Gamma = \left\{\Gamma: \Delta_{B(b, C^{-1}\alpha)}(\Gamma, \Gamma_i) < C_1\delta, \ i = 1, 2, 3; \right.
\]

\[
d(\Gamma \cap B_0, \Gamma_i \cap B_0) > t, \ i = 1, 2, 3;
\]

\[
\Gamma^\delta \cap \Gamma^\delta_i \cap B_0 \neq \emptyset, \ i = 1, 2, 3;
\]

\[
dist(\Gamma^\delta \cap \Gamma^\delta_i \cap B_0) > C_3\sqrt{\delta/t}, \ i \neq j\right\}.\]

(4.7)

Informally, \(Y\) is the collection of curves that are almost tangent to each of the curves \(\Gamma_1, \Gamma_2, \Gamma_3\), with the additional requirement that the three regions of almost tangency not be too close to each other.

If we identify \(\Phi\)-circles \(\Gamma\) with points \((x_0, r_0) \in \mathbb{R}^3\) then

\[(4.8) \quad Y \text{ is the union of two sets, each of diameter } \lesssim t.\]

This is Lemma 3.1(ii) in [7].

**Property 4.5.** For three fixed curves \(\Gamma_1, \Gamma_2, \Gamma_3\), and a given curve \(\Gamma = \Gamma(x_0, r_0)\), we say that \(\Phi\) is \(\Gamma\)-adapted if there exist points \(a_1, a_2, a_3\), with \(a_j \in \Gamma_j\) such that

\[|a_j - \xi_j(x_0)| \leq C^{-1}\sqrt{\delta/t},\]

and

\[\Phi(x, a_1) = 0,\]

\[\nabla_x \Phi(x, a_2) = (e \cdot (a_2 - a_1))\beta\]

for all \(x\), where \(e\) is a unit tangent vector to \(\Gamma_1\) at \(a_1\), \(\beta\) is a vector independent of \(y\) with \(|\beta| \sim 1\), and

\[\xi_i(x_0) = \xi(x_i, r_i, x_0).\]
Remark 4.6. Informally, the notion of a $\Gamma$-adapted defining function is a way of getting around the problem that we are forced to work with a defining function $\Phi$, but we are actually interested in its level sets $\{\Phi(x, \cdot) = r\}$. Thus we are free (within certain constraints to be dealt with below) to modify $\Phi$ provided that our new defining function has the same level sets as the old one. Choosing a $\Gamma$-adapted defining function (provided a suitable one exists) simplifies many of the technicalities in our estimates.

Lemma 3.6 in [7] tells us that if $\Gamma \in Y$ then by pre-composing $\Phi$ with suitable diffeomorphisms, a $\Gamma$-adapted defining function $\Phi$ exists which satisfies uniform derivative bounds, and this function $\Phi$ has the same level sets as our original $\Phi$ (i.e., it gives rise to the same $\Phi$-circles), so the corresponding maximal functions are identical (the adapted defining function may not be algebraic, but this will not affect our analysis).

Now, if $\Phi$ is $\Gamma$-adapted, define

$$T(x) = \begin{pmatrix} \nabla_x \Phi(x, \xi_1(x)) & -1 \\ \nabla_x \Phi(x, \xi_2(x)) & -1 \\ \nabla_x \Phi(x, \xi_3(x)) & -1 \end{pmatrix}.$$  

Informally, if we fix a choice of $\Gamma$ and select a defining function adapted to $\Gamma$, then for $x$ in a neighborhood of $x_0$, $T(x)$ describes how changing $x$ affects how close $\Gamma(x, r_0)$ is to being tangent with each of $\Gamma_1, \Gamma_2, \Gamma_3$.

Lemma 3.8 in [7] tells us that when restricted to each connected component of $Y$ (individually), $T$ is boundedly conjugate to its linear part, i.e., if $\Gamma$ and $\tilde{\Gamma}$ lie in the same connected component of $Y$, then

$$T(x_0)T(\tilde{x}_0)^{-1} = I + E(\tilde{x}_0),$$

where (say) $\|E(\tilde{x}_0)\| < 1/100$. Furthermore, for the same choices of $\Gamma$ and $\tilde{\Gamma}$,

$$|\xi_1(\tilde{x}_0) - \xi_1(x_0)| \lesssim \sqrt{\delta/t}.$$ 

Equation (4.11) is a consequence of equation (45) in [7] once we note that if $\tilde{\Gamma} \in Y$ is in the same connected component as $\Gamma \in Y$, then since $T$ is boundedly conjugate to its linear part, $|T(x_0)(\tilde{x}_0 - x_0, \tilde{r}_0 - r_0)| < C\delta$.

Property 4.7 (Bounds on intersection area). Let $\Gamma$ and $\tilde{\Gamma}$ be $\Phi$-circles. Then,

$$|\Gamma^\delta \cap \tilde{\Gamma}^\delta \cap B(b, C^{-2}\alpha)| \lesssim \frac{\delta^2}{(d(\Gamma, \tilde{\Gamma}) + \delta)^{1/2}} (\Delta_{B(b, C^{-1}\alpha)}(\Gamma, \tilde{\Gamma}) + \delta)^{1/2},$$

$$\text{diam}(\Gamma^\delta \cap \tilde{\Gamma}^\delta \cap B(b, C^{-2}\alpha)) \lesssim \left( \frac{\Delta_{B(b, C^{-1}\alpha)}(\Gamma, \tilde{\Gamma}) + \delta}{d(\Gamma, \tilde{\Gamma}) + \delta} \right)^{1/2}.$$ 

This is Lemma 3.1(i) in [7].
As noted above, when \( \Phi(x, y) = |x - y| \), then \( S_{\Gamma, B(b, \alpha)} \) is a section of the right-angled light cone with focus at \((x_0, r_0)\). We shall establish several lemmas that show that certain key properties of light cones are preserved when we consider the set \( S_{\Gamma, B(b, \alpha)} \) for \( \Phi \) a general defining function satisfying the requirements from Theorem 1.1.

**Lemma 4.8.** Let \( \Gamma \) and \( \tilde{\Gamma} \) be \( \Phi \)-circles with

\[
\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) < C^{-1} |x_0 - \tilde{x}_0|.
\]

Then there exists \( \Gamma' \) with \( x'_0 = \tilde{x}_0, \ |r'_0 - \tilde{r}_0| \lesssim \Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) \) such that

\[
\Gamma' \in S_{\Gamma, B(b, \alpha)}.
\]

Furthermore,

\[
\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) \lesssim \text{dist}(S_{\Gamma, B(b, \alpha)}, \tilde{\Gamma}) \lesssim \Delta_{B(b, 1/C^{-1} \alpha)}(\Gamma, \tilde{\Gamma}).
\]

**Remark 4.9.** Note that we have to use different sets \( X \) in the subscript of \( \Delta \) on the right and left sides of (4.16). In the case where \( \Phi(x, y) = |x - y| \) (and thus we can define \( \Phi \) over (say) a large dilate of the unit circle),

\[
\Delta_{B(0, 100)}(\Gamma, \tilde{\Gamma}) = \| |x_0 - \tilde{x}_0| - |r_0 - \tilde{r}_0| \|
\]

provided \( \Gamma \) and \( \tilde{\Gamma} \) lie in suitably restricted sets, and if two circles are nearly incident, we can always change one of them slightly so that they are exactly incident. In the more general case we are considering, however, it may not always be possible to make two almost incident curves exactly incident by changing one of them slightly; it is possible that when we try to move one of the curves to make the two curves incident, the “point of incidence” occurs outside the domain of definition of \( \Phi \) (and thus there is no point of incidence). Thus, we need to be more careful about how we define incidence and almost incidence. This consideration will occur frequently in the lemmas below, and it will significantly lengthen our analysis.

**Proof.** By (3.4) and (3.5), in order to obtain (4.16), it suffices to establish the estimate

\[
\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) \lesssim \text{dist}(S_{\Gamma, B(b, \alpha)}, \tilde{\Gamma}) \lesssim \Delta_{B(b, 1/C^{-1} \alpha)}(\Gamma, \tilde{\Gamma}).
\]

First, note that \( \Delta_{B(b, \alpha)}(\cdot, \cdot) \) is jointly smooth in both variables with uniformly bounded derivatives. Since \( \Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) = 0 \) for \( \Gamma' \in S_{\Gamma, B(b, \alpha)} \), we immediately obtain the first inequality in (4.17). The second inequality in (4.17) follows from (4.15), which we shall now prove.

Straighten out \( \Phi \) around \( \tilde{x}_0 \). From Property 4.3 of \( \Phi \), there exists \( \xi \in B(b, \alpha) \cap \Gamma' \) such that

\[
\nabla_y \Phi(x_0, \xi) \wedge \nabla_y \Phi(\tilde{x}_0, \xi) = 0,
\]
i.e. (in straightened out coordinates),
\[
\frac{\nabla_y\Phi(x_0, \xi)}{|\nabla_y\Phi(x_0, \xi)|} = (\pm 1, 0),
\]
and
\[
|\Phi(\tilde{x}, \xi) - \tilde{r}_0| \lesssim \Delta_{B(b, C^{-1} \alpha)}(\Gamma, \tilde{\Gamma}),
\]
where here and below the implicit constants are uniform in the choice of \(\Gamma\) and \(\tilde{\Gamma}\) provided (4.14) is satisfied uniformly. Thus if we select \(x'_0 = \tilde{x}_0, r'_0 = \tilde{r}_0 + \Phi(\tilde{x}_0, \xi)\) then \(\xi\) lies on \(\Gamma'\), which establishes (4.15).

Corollary 4.10. \(S_{\Gamma, B(b, \alpha)}\) is a smooth manifold and \(\dim(S_{\Gamma, B(b, \alpha)}) \geq 2\).

Proof. Let \((\tilde{x}_0, \tilde{r}_0) \in S_{\Gamma, B(b, \alpha)}\). Then for \(C\) sufficiently large, \(B(0, 1/C)\) embeds into \(S_{\Gamma, B(b, \alpha)}\) in a neighborhood of \((\tilde{x}_0, \tilde{r}_0)\) via the embedding \((x, r) \mapsto (x + \tilde{x}_0, r')\), where \(r'\) is as described in Lemma 4.8.

Corollary 4.11. There exists \(C_0\) such that for all \(\Phi\)-circles \(\Gamma\), all \((x, r) \in S_{\Gamma, B(b, \alpha)}\), and all \(t < C^{-1}|x - x_0|\),
\[
\pi_x(S_{\Gamma, B(b, \alpha)}) \cap \{(x', r'): |x - x'| < t, |r - r'| < C_0 t\} = \{x': |x - x'| < t\},
\]
i.e., the cylindrical section centered at \((x, r) \in S_{\Gamma, B(b, \alpha)}\) of radius \(t\) and height \(Ct\) contains all of (or possibly all of one of the sheets of) \(S_{\Gamma, B(b, \alpha)}\) confined to the corresponding truncated cylinder.

5. Counting incidences between bipartite pairs of curve families

Recall the definitions of a \(t\)-bipartite pair \((W, B)\), a \((\delta, t)\)-rectangle, and a rectangle of type \((\gtrsim \mu, \gtrsim \nu)\) relative to \((W, B)\) (Definition 2.4).

Definition 5.1. We shall say that a \((\delta, t)\) rectangle \(R\) is of type \((\sim \mu, \sim \nu)\) if it is of type \((\gtrsim \mu, \gtrsim \nu)\), but is neither of type \((\gtrsim C\mu, \gtrsim \nu)\) nor \((\gtrsim \mu, \gtrsim C\nu)\) for some absolute constant \(C\) which shall be determined later.

Definition 5.2. We say that two \((\delta, t)\)-rectangles are close if there is a \((2\delta, t)\) rectangle containing both of them. We say that two \((\delta, t)\)-rectangles are comparable if there is a \((C_0 \delta, t)\)-rectangle containing both of them.

For \((W, B)\) a \(t\)-bipartite pair with \(t > C\delta\) and \(X\) a set, define
\[
\mathcal{I}_X = \{(\Gamma, \tilde{\Gamma}) \in (W, B): \Delta_X(\Gamma, \tilde{\Gamma}) < \delta\},
\]
\[
\tilde{\mathcal{I}}_X = \{(\Gamma, \tilde{\Gamma}) \in (W, B): \Delta_X(\Gamma, \tilde{\Gamma}) < C\delta\},
\]
for some constant \(C\) to be determined later, where we recall that \(\Delta_X\) is defined in (2.3).
We shall state and prove a series of lemmas that are analogous to Lemmas 1.5–1.16 in [15]. If the proof of a lemma is the same as that of the corresponding lemma in [15], we shall omit it. Throughout the discussion below, $(W, B)$ is a $t$-bipartite pair with $\#W = m$, $\#B = n$.

**Lemma 5.3.**

(i) If $\Delta_{B(b, C^{-1}a)}(\Gamma, \tilde{\Gamma}) < \delta$, then there exists a $(\delta, t)$-rectangle $R \subset B(b, \alpha)$ such that $\Gamma$ and $\tilde{\Gamma}$ are tangent to any $(\delta, t)$-rectangle close to $R$.

(ii) Conversely, if $\Gamma, \tilde{\Gamma}$ are tangent to a common $(\delta, t)$-rectangle $R \in B(b, \alpha)$, then $\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) \leq C\delta$, and if $\Gamma$ and $\tilde{\Gamma}$ are tangent to comparable $(\delta, t)$-rectangles $R, R' \in B(b, \alpha)$ then $\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) \lesssim \delta$.

**Lemma 5.4.** Let $\Gamma \in W$ and $\tilde{\Gamma} \in B$. Then there are at most $O(1)$ incomparable $(\delta, t)$-rectangles $R \subset B(b, \alpha)$ tangent to both $\Gamma$ and $\tilde{\Gamma}$.

**Proof.** Since $d(\Gamma, \tilde{\Gamma}) \sim t$, (4.12) gives us the bound

\[(5.1) \quad |B'(b', C^{-1}a) \cap \Gamma \cap \tilde{\Gamma}| \lesssim \delta^{3/2}t^{-1/2}\]

for all $b'$ in a sufficiently small neighborhood of $b$. Each $(\delta, t)$-rectangle has area $\sim \delta^{3/2}t^{-1/2}$ and incomparable $(\delta, t)$-rectangles are pairwise disjoint. The lemma follows by applying (5.1) to $O(1)$ choices of $b' = b + t_i$. \hfill $\square$

**Lemma 5.5.**

(i) Let $R \subset B(b, \alpha)$ be a collection of pairwise nonclose rectangles. Then

$$\#I_{B(b, \alpha)} \gtrsim \#\{(R, \Gamma, \tilde{\Gamma}) \in R \times B \times W: \Gamma \text{ and } \tilde{\Gamma} \text{ are tangent to } R\}.$$

(ii) There exists a collection $R$ of pairwise incomparable $(\delta, t)$-rectangles $R \in B(b, \alpha)$ such that

$$\#I_{B(b, C^{-1}a)} \lesssim \#\{(R, \Gamma, \tilde{\Gamma}) \in R \times B \times W: \Gamma \text{ and } \tilde{\Gamma} \text{ are tangent to } R\}.$$

**Proof.** The first statement is immediate. The second statement can be proved in the same way as Lemma 1.7 in [15] with (4.4) and (4.5) used in place of the analogous equations in [15]. \hfill $\square$

**Lemma 5.6.** Let $\Gamma_1, \Gamma_2, \Gamma_3$ be three $\Phi$-circles. Let $R$ be a collection of pairwise incomparable rectangles $R \in B(b, \alpha)$ with the property that for each $R \in R$ there is a $\Phi$-circle $\Gamma$ such that:

- $d(\Gamma, \Gamma_i) \geq t$, $i = 1, 2, 3$.
- $\Gamma$ and $\Gamma_1$ are tangent to $R$.
- There exist two $(\delta, t)$-rectangles $R_2, R_3 \in B(b, \alpha)$ such that $\Gamma$ and $\Gamma_1$ are tangent to $R_i$, $i = 2, 3$, and such that $R_1, R_2, R_3$ are pairwise incomparable.

Then $\#R \lesssim 1$. 

Proof. We shall establish the proof with the additional restriction that \( R \) must lie in \( B(b', C^{-2} \alpha) \) for \( b' \) in a sufficiently small neighborhood of \( b \). Once this has been established, we can recover the full result by selecting \( O(1) \) choices of \( b' \) such that \( B(b, \alpha) \subset \bigcup_b B(b', C^{-2} \alpha) \).

Let \( R \in \mathcal{R} \) and let \( \Gamma \) be a \( \Phi \)-circle satisfying the above conditions. Then we must have \( \Gamma \in Y \), where \( Y \) is as defined in (4.7); indeed the above requirements on \( \Gamma \) are precisely those needed to ensure that \( \Gamma \in Y \). By (4.12),

\[
(5.2) \quad \Gamma \cap \Gamma_1 \cap B(b', C^{-2} \alpha) \subset B(\xi(x_0, r_0, x_1), C \delta^{1/2} t^{-1/2}).
\]

Now, let \( \Gamma_0 \in Y \) and let \( \tilde{\Phi} \) be a \( \Gamma_0 \)-adapted defining function with the same level sets as \( \Phi \). Since \( \tilde{\Phi} \) has the same level sets as \( \Phi \) and the gradient of \( \tilde{\Phi} \) is comparable to that of \( \Phi \), it suffices to prove the lemma for \( \tilde{\Phi} \). However, by (4.11) we have that if \( \Gamma \) is in the same connected component of \( Y \) as \( \Gamma_0 \) then

\[
(5.3) \quad |\xi(x_1, r_1, x_0) - \xi(x_1, r_1, x)| \lesssim \sqrt{\delta/t}.
\]

Since \( Y \) contains only two connected components, (5.2) and (5.3) imply that

\[
(5.4) \quad \bigcup_{(x_0, r_0) \in Y} \Gamma(x_0, r_0) \cap \Gamma_1 \cap B(b', C^{-2} \alpha) \\
\quad \subset \left( B(z_0, C \delta^{1/2} t^{-1/2}) \cap \Gamma_1 \right) \cup \left( B(z_1, C \delta^{1/2} t^{-1/2}) \cap \Gamma_1 \right),
\]

where \( z_0, z_1 \) are points in the two connected components of \( Y \) respectively. In particular, the set on the right hand side of (5.4) has measure \( \lesssim \delta^{3/2} t^{-1/2} \). Since every \( R \in \mathcal{R} \) must lie in this set, and pairwise incomparable rectangles must be disjoint, we obtain \( \# \mathcal{R} \lesssim 1 \). \( \square \)

**Lemma 5.7.** Let \( \Gamma \) and \( \tilde{\Gamma} \) be \( \Phi \)-circles with \( d(\Gamma, \tilde{\Gamma}) = t > C \delta \) and \( r_0 \geq \tilde{r}_0 \). Let \( R, \tilde{R} \in B(b, C^{-1} \alpha) \) be comparable \((\delta, t)\)-rectangles with \( \Gamma \) and \( \tilde{\Gamma} \) tangent to \( R \) and \( \tilde{R} \), respectively. Then,

(i) \( \tilde{\Gamma} \cap B(b, C^{-1} \alpha) \) is contained in the \( C \delta \)-neighborhood of \( \{ y \in B(b, \alpha) : \Phi(x_0, y) \leq r_0 \} \).

(ii) For any constant \( A \) there is a constant \( C(A) \) such that the cardinality of any set of pairwise incomparable \((\delta, t)\)-rectangles \( R \in B(b, C^{-1} \alpha) \) each of which is tangent to \( \Gamma \) and intersects the \( A \delta \)-neighborhood of \( \{ y \in B(b, \alpha) : \Phi(x_0, y) \leq r_0 \} \)

does not exceed \( C(A) \).

**Proof.** Straighten \( \Phi \) around \( x_0 \). By Lemma 5.3.(ii), with \( \alpha \) replaced by \( C^{-1} \alpha \), we have \( \Delta_{B(b, C^{-1} \alpha)}(\Gamma, \tilde{\Gamma}) \leq C' \delta \). Thus if we choose the value of \( C \) in the statement of the lemma to be sufficiently large (depending on \( C' \)), then \( |x_0 - \tilde{x}_0| > \)
$C'' \Delta_B(b, C^{-1}a) (\Gamma, \tilde{\Gamma})$, so by Property 4.3 of the cinematic curvature, there exists a unique point $\xi(x_0, r_0, x_0) \in \tilde{\Gamma}$ satisfying (4.4), i.e.,
\[ \nabla y \Phi(x_0, \xi) = (0, \pm 1), \]
so $\xi^{(1)}$ is the point where the function $y^{(1)} \mapsto \Phi(x_0, (y^{(1)}, y^{(2)}))$ achieves its maximum in the domain $(y^{(1)}, y^{(2)}) \in B(b, \alpha)$, where $y^{(2)} = y^{(2)}(y^{(1)})$ is implicitly defined by $(y^{(1)}, y^{(2)}(y^{(1)})) \in \tilde{\Gamma}$ (we can verify without difficulty that this is well-defined). By (4.5) (noting that in the straightened out coordinate system, $\Gamma = \{y^{(2)} = 0\} \cap U_2'$),
\[ \Phi(x_0, \xi) \lesssim \Delta_B(b, C^{-1}a) (\Gamma, \tilde{\Gamma}) \lesssim \delta, \]
and thus for an appropriate choice of $C$,
\[ \tilde{\Gamma} \cap U_2' \subset \{y^{(2)} < C\delta\}. \]

Returning to our original coordinate system, this is Statement (i) of the lemma.

To obtain the second statement, note that by the same reasoning as above,
\begin{equation}
(5.5) \quad \Gamma^{C\delta} \cap \left( \{y \in B(b, \alpha) : \Phi(x_0, y) \leq r_0\} + B(0, A\delta) \right) \\
\subset \Gamma^{C(A)\delta} \cap \tilde{\Gamma}^{C(A)\delta} \cap B(b, \alpha)
\end{equation}
for a suitable constant $C(A)$, where the $+$ in the above equation denotes the Minkowski sum. The result then follows from (4.12) and the fact that incomparable rectangles are disjoint. \hfill \Box

**Lemma 5.8.**

(i) The cardinality of any set of $(\sim \mu, \sim \nu)$ rectangles is $\lesssim \frac{m^{2/3} n^{2/3}}{\mu \nu}$.  

(ii) The cardinality of any set of $(\gtrsim \mu, \gtrsim \nu)$ rectangles is $\lesssim \frac{m^{2/3} n^{2/3}}{\mu \nu} + \frac{n}{\nu} \log \frac{m}{\mu}$.

**Remark 5.9.** Recall that a rectangle of type $(\gtrsim \mu, \gtrsim \nu)$ is a rectangle that is incident to at least $C\mu$ curves in $W$ and to at least $C\nu$ curves in $B$ for some absolute constant $C$ (a rectangle of type $(\sim \mu, \sim \nu)$ is defined similarly), so the statement of the lemma is well-defined.

**Proof.** Combined with the previous lemmas, statement (i) is just the graph-theoretic statement, due to Kövari, Sós, and Turán in [8], that an $m \times n$ matrix with entries 0 and 1 which has a forbidden $2 \times 3$ submatrix of 1s has $\lesssim mn^{2/3}$ 1s in total. Statement (ii) is obtained from statement (i) by dyadic summation. \hfill \Box

The following lemma is the analogue of Lemma 1.11 in [15]. The proof is identical.

**Lemma 5.10.** Let $(W, B)$ be a $t$-bipartite pair that has no $(\gtrsim 1, \gtrsim \nu_0)$ or $(\gtrsim \mu_0, \gtrsim 1)$ rectangles $R \in B(b, \alpha)$. Then,
\begin{equation}
#I_{B(b, C^{-1}a)} (W, B) \lesssim \mu_0^{1/3} n m^{2/3} \log \nu_0 + \nu_0 m \log \mu_0.
\end{equation}
Lemma 5.11. Let \((W, B)\) be a \(t\)-bipartite pair with \(#B = n\). Randomly select a subset \(D \subset B\) with \(#D = N < \frac{1}{C}n\), (we shall call the elements of \(D\) dividing circles), and let \(S = \{S_{\Gamma, B(b,\alpha)}: \Gamma \in D\}\). Then with high probability (relative to our random selection of \(D \subset B\)), we can partition

\[
W = W^* \sqcup \bigsqcup_{i=1}^M W_i
\]

so that the decomposition has the following properties:

(i) \(M \lesssim N^3 \log N\).

(ii) For each \(i\),

\[
\#\{\Gamma \in B: \Delta_{B(b, C^{-1}\alpha)}(\Gamma, \tilde{\Gamma}) \leq C\delta \text{ for some } \tilde{\Gamma} \in W_i\} \lesssim \frac{n \log n}{N}.
\]

(iii) For each \(\Gamma \in W^*\) there exists a dividing \(\Phi\)-circle \(\Gamma\) such that

\[
\Delta_{B(b, \alpha)}(\Gamma, \tilde{\Gamma}) \lesssim \delta.
\]

Remark 5.12. The implicit constants appearing above depend only on \(\Phi\) and the probability that a randomly selected \(D \subset B\) has the desired properties. In particular, by worsening the implicit constants we can make the probability arbitrarily close to 1.

Proof. Perform the cell decomposition of the arrangement \(D\), as described in Lemma 3.4. Let

\[
W^* = \{\Gamma \in W: \text{dist}(\Gamma, S_{\Gamma, B(b,\alpha)}) \leq C\delta \text{ for some } \tilde{\Gamma} \in D\},
\]

and for each \(i = 1, \ldots, M\), let

\[
W_i = \{\Gamma \in W \setminus W^*: \Gamma \in \Omega_i\}.
\]

If some \(\Gamma\) is present in more than one \(W_i\), remove it from all but one of the \(W_i\) (the choice is irrelevant). We shall now verify that this decomposition satisfies the properties claimed in the lemma. Property (i) is immediate from Lemma 3.4, and property (iii) follows from (4.16). Thus it remains to verify property (ii). The idea is to show that if \(\Gamma \in B\) satisfies \(\Delta_{B(b, C^{-1}\alpha)}(\Gamma, \tilde{\Gamma}) \leq C\delta\) for some \(\tilde{\Gamma} \in W_i\), then \(\Gamma\) must lie in the corresponding cell \(\Omega_i\) of the cell decomposition. Once this has been established we can use (3.7) to control the number of times this can occur.

Suppose \(\Gamma \in W_i, \Gamma \in B\) with \(\Delta_{B(b, C^{-1}\alpha)}(\Gamma, \tilde{\Gamma}) \leq C\delta\). Then by (4.16),

\[
\text{dist}(\Gamma, S_{\Gamma, B(b,\alpha)}) \leq C\delta,
\]
and so we can select \(\Gamma' \in S_{\Gamma, B(b,\alpha)}\) with \(d(\Gamma', \Gamma) \leq C\delta\) (for a possibly larger constant \(C\)). Furthermore, since \((W, B)\) is a \(t\)-bipartite pair, we have that \(|x_{0}' - \bar{x}_0| > \gamma > \delta\), and thus by Corollary 4.11, there exists \(r_0''\) such that

\[
\Gamma(x_{0}', r_0'') \in S_{\Gamma, B(b,\alpha)} \cap \{ (x', r'): |x_{0}' - \bar{x}_0| < C_1 \delta, |r'' - \bar{r}_0| < C_2 \delta \}.
\]
However, (5.10) implies that $|r''_0 - r_0| < C_2\delta$, and selecting constants appropriately in the definition of $W^*$, this is less than $\text{dist}(\Gamma, S_{\Gamma''}, B(b, \alpha))$ for any $\Gamma'' \in D$. Since the boundary of each cell $\Omega$ consists only of dividing surfaces $S_{\Gamma''}, B(b, \alpha)$ and vertical manifolds (2-dimensional surfaces that can be written as unions of vertical line segments), we conclude that $(x_0', r''_0) \in \Omega_i$, and thus

$$S_{\Gamma, B(b, \alpha)} \cap \Omega_i \neq \emptyset.$$ 

Equation (3.7) bounds the number of dividing surfaces that can intersect each cell $\Omega_i$, and this in turn gives us property (ii).

**Lemma 5.13.** With high probability,

$$\#W^* \lesssim \frac{n \#\hat{I}_{B(b, \alpha)}(W, B)}{N}.$$ 

**Proof.** This follows from property (iii) of Lemma 5.11. Indeed, the probability of a given $\Gamma \in W$ being in $W^*$ is bounded by

$$\frac{n}{N} \{ \hat{\Gamma} \in B: \Delta_{B(b, \alpha)}(\Gamma, \hat{\Gamma}) < C\delta \},$$

so the expected size of $W^*$ is $\frac{n \#\hat{I}_{B(b, \alpha)}(W, B)}{N}$, from which the result follows. \qed

**Definition 5.14.** We define a cluster of $\Phi$-circles analogously to Wolff’s definition in [15]: A cluster is a subset $C \subset W$ (or $B$) with the property that there exists a $(\delta, t)$-rectangle $R$ such that every $\Gamma \in C$ is tangent to a $(\delta, t)$-rectangle comparable to $R$.

**Lemma 5.15.** Let $C \subset W$ be a cluster and let $\Gamma \in B$. Then then any set of pairwise incomparable $(\delta, t)$-rectangles each of which is tangent to some circle in $C$ and to $\Gamma$ has cardinality $O(1)$.

**Remark 5.16.** Lemma 5.7 is used to prove this lemma. See Lemma 1.14 of [15] for details.

**Lemma 5.17.** Given a value of $\mu_0$, we can write

$$W = W_g \sqcup W_b,$$

where

(i) $W_g$ and $B$ have no $(\delta, t)$-rectangles of type $(\gtrsim \mu_0, \gtrsim 1)$.

(ii) $W_b$ is the union of $\lesssim \frac{\#W}{\mu_0} (\log m)(\log n)$ clusters.

**Lemma 5.18.** Let $(W, B)$ be a $t$-bipartite pair with $m = |W|, n = |B|$. Let $R$ be a set of pairwise incomparable $(\gtrsim \mu, \gtrsim \nu)$ $(\delta, t)$-rectangles contained in $B(b, \alpha)$.

For any $\epsilon > 0$,

$$\#R \lesssim_\epsilon (mn)^{\gamma} \left( \frac{mn}{\mu \nu} \right)^{3/4} + \frac{m}{\mu} + \frac{n}{\nu}.$$
In order to prove Lemma 5.18, it suffices to consider the case where $\mu = \nu = 1$ and establish the bound

$$(5.14) \quad \# \mathcal{R} \lesssim \epsilon ((mn)^{3/4} + m \log n + n \log m).$$

To obtain (5.13) from (5.14) we apply a random sampling argument. The details of this random sampling argument are on page 1253 of [15], so we shall not reproduce them here. We shall call the $\Phi$-circles $\Gamma \in \mathcal{W}$ “white” $\Phi$-circles and those in $\mathcal{B}$ “black” $\Phi$-circles. By Lemma 5.4, each pair $(\Gamma, \tilde{\Gamma}) \in (\mathcal{W}, \mathcal{B})$ of white and black $\Phi$-circles are jointly incident to at most $O(1)$ incomparable $(\delta, t)$-rectangles, so $\# \mathcal{R} \lesssim mn$. Thus if $(mn)^{1/C} \log(mn)$ then (5.14) holds immediately (with an implicit constant depending on $C$). Thus we may assume

$$(5.15) \quad (mn)^{1/C} > \log(mn)$$

for some fixed choice of $C$ which will be determined below.

We shall closely follow [15] and substitute our lemmas above for Wolff’s analogous ones. Wolff’s induction argument allows him to control the number of incomparable $(\delta, t)$-rectangles of type $(\geq 1, \geq 1)$ relative to a collection $(\mathcal{W}, \mathcal{B})$ over the region $B(b, \alpha)$ if he has similar control over smaller collections $(\mathcal{W}', \mathcal{B}')$. Our argument will allow us to control the number of incomparable $(\geq 1, \geq 1)$ rectangles in a small region $B(b, C^{-1} \alpha)$ if we have control over the number of incomparable rectangles in a much larger region $B(b, \alpha)$, but luckily we only require this control for smaller collections of circles. Since the control is uniform in $b$, we can apply this result to finitely many translates $\{b + t_i\}$ of $b$ to recover the result over the larger region $B(b, \alpha)$, which allows us to iterate the induction step. We shall focus on the key steps where our arguments differ from Wolff’s, and refer readers to [15] for the details of those arguments which are identical.

To simplify our notation, we will employ the following definition:

**Definition 5.19.** For $(\mathcal{W}, \mathcal{B})$ a $t$-bipartite pair and $X \subset \mathbb{R}^2$, define $\mathcal{R}_X(\mathcal{W}, \mathcal{B})$ to be the maximum possible cardinality of a set of pairwise incomparable rectangles of type $(\geq 1, \geq 1)$ that are contained in the set $X$.

Assume (5.14) holds for all pairs $(\mathcal{W}', \mathcal{B}')$ with $(\# \mathcal{W}') (\# \mathcal{B}') < mn/2$. The base case of the induction is taken care of by (5.15).

If $m \leq n^{1/3+\epsilon}$ or vice versa, then Lemma 5.18 follows from Lemma 5.8. Thus we may assume

$$(5.16) \quad m^{1/3+\epsilon} < n < m.$$ 

Let $\mathcal{W} = \mathcal{W}_g \cup \mathcal{W}_b$, $\mathcal{B} = \mathcal{B}_g \cup \mathcal{B}_b$ be the decomposition from Lemma 5.17 with $\mu_0 = \nu_0 = (mn)^{3/4}$. From property (ii) of the decomposition and Lemma 5.15, we have

$$(5.17) \quad \mathcal{R}_{B(b, \alpha)}(\mathcal{W}_b, \mathcal{B}) < \log m \log n (mn)^{3/4},$$

$$(5.18) \quad \mathcal{R}_{B(b, \alpha)}(\mathcal{W}, \mathcal{B}_b) < \log m \log n (mn)^{3/4}.$$
These quantities are $< \frac{1}{1000} (mn)^\epsilon (mn)^{3/4}$ provided that we choose the appropriate constant $C$ in (5.15).

We shall now obtain the bound

$$R_{B'(b, C^{-1} \alpha)}(W_g, B_g) \leq C_e (mn)^\epsilon (mn)^{3/4} C_0^{-1},$$

where we can make $C_0$ arbitrarily large at the cost of increasing $C_e$. Furthermore, this bound will be independent of the choice of $b' \in B(b, \alpha)$. Thus we shall apply (5.19) with $b' = b + t_i$ for $\{t_i\}$ a finite family of translates such that for every point $x \in B(b, \alpha)$, there exists an index $i$ such that $x$ is contained in $B(b + t_i, C^{-1} \alpha)$ and is distance at least $C t$ from the boundary, and thus any $(\delta, t)$-rectangle contained in $B(b, \alpha)$ is contained in some $B(b + t_i, C^{-1} \alpha)$. We thus have

$$R_{B(b, \alpha)}(W_g, B_g) \leq \sum_{i} R_{B(b + t_i, C^{-1} \alpha)}(W_g, B_g).$$

Thus if we apply (5.19) for each $t_i$ and select $C_0$ sufficiently large we obtain

$$R_{B(b, \alpha)}(W_g, B_g) \leq \frac{1}{1000} C_e (mn)^\epsilon (mn)^{3/4}. $$

Combining (5.21), (5.17), and (5.18) and using Lemma 5.5 we obtain (5.14). It thus suffices to prove (5.19).

Write $W_g = W_0 \sqcup \bigcup_{i=1}^M W_i$ as given by Lemma 5.11, with $\alpha$ replaced by $C^{-1} \alpha$ and selecting a value of $N$ satisfying

$$C \log(mn)^{1/\epsilon} < N < C^{-1} \min\{n^{3/4} m^{-1/4} \log(mn), m^{1/4} n^{-1/12} \log(mn)\}. $$

Such a value of $N$ exists by assumption (5.16) and by selecting a sufficiently large constant in (5.15).

We claim:

$$\#W_g^* \leq \frac{1}{1000 C_0^*} \#W_0. $$

Indeed, $(W_g, B_g)$ contain no $(\delta, t)$-rectangles of type $(\geq \mu_0, \geq 1)$ or $(\geq 1, \geq \nu_0)$ so by Lemma 5.10 (with $\delta$ replaced by $C \delta$ for a suitable constant $C$),

$$\#T_{B(b, C^{-1} \alpha)}(W_g, B_g) \leq m^{5/4} n^{1/4} \log m + m^{3/4} n^{13/12} \log n, $$

and thus by Lemma 5.13 (recall that now $\alpha$ is replaced by $C^{-1} \alpha$ and $C^{-1} \alpha$ is replaced by $C^{-2} \alpha$) we can select our decomposition of $W_g$ so that

$$\#W_g^* \leq \frac{n}{N} (m^{5/4} n^{1/4} \log m + m^{3/4} n^{13/12} \log n). $$

Using (5.22) and selecting a sufficiently large constant in (5.15) (of course the choice of constant in (5.15) will depend on the desired constant $C_0$ in (5.23)) we obtain (5.23). Since $(\#W_g^*) (\#B) < mn/2$ we can apply the induction hypothesis to obtain

$$R_{B(b, \alpha)}(W_g^*, B_g) \leq \frac{1}{1000 C_0^*} C_e (mn)^\epsilon ((mn)^{3/4} + m \log n + n \log m). $$
Now, for each $i$ let
\begin{equation}
B_i^g = \{ \Gamma \in B_g : \Delta_{B(b, C^{-2} \alpha)}(\Gamma, \tilde{\Gamma}) < C\delta \text{ for some } \tilde{\Gamma} \in \mathcal{W}_g^i \}.
\end{equation}

Item (ii) in Lemma 5.11 implies
\begin{equation}
\#B_i^g \lesssim \frac{n \log n}{N}.
\end{equation}

Now, we can apply the induction hypothesis to the pair $(\mathcal{W}_g^i, B_i^g)$ to conclude
\begin{equation}
\mathcal{R}_{B(b, \alpha)}(\mathcal{W}_g^i, B_i^g) \leq C_{\epsilon} \left[ (\#\mathcal{W}_g^i)(\#B_i^g) \right]^{\epsilon} \left[ (\#\mathcal{W}_g^i)(\#B_i^g) \right]^{3/4} C_0^{-1}.
\end{equation}

However, $B_i^g$ was selected so that
\begin{equation}
\mathcal{R}_{B(b, C^{-2} \alpha)}(\mathcal{W}_g^i, B_i^g) \leq \mathcal{R}_{B(b, \alpha)}(\mathcal{W}_g^i, B_i^g),
\end{equation}

and thus (5.28) implies
\begin{equation}
\mathcal{R}_{B(b, C^{-2} \alpha)}(\mathcal{W}_g^i, B_i^g) \leq \mathcal{R}_{B(b, \alpha)}(\mathcal{W}_g^i, B_i^g),
\end{equation}

and thus (5.28) implies
\begin{equation}
\mathcal{R}_{B(b, C^{-2} \alpha)}(\mathcal{W}_g^i, B_i^g) \leq C_{\epsilon} \left[ (\#\mathcal{W}_g^i)(\#B_i^g) \right]^{\epsilon} \left[ (\#\mathcal{W}_g^i)(\#B_i^g) \right]^{3/4} C_0^{-1}.
\end{equation}

Summing (5.29) over the $M \lesssim N^3 \log N$ choices of $i$ and applying Hölder’s inequality (see pages 1252–3 of [15] for the details), we obtain
\begin{equation}
\sum_i \mathcal{R}_{B(b, C^{-2} \alpha)}(\mathcal{W}_g^i, B_i^g)
\leq \frac{1}{1000} C_{\epsilon} (mn)^{\epsilon} \left( (mn)^{3/4} + m \log n + n \log m \right).
\end{equation}

Combining (5.30), (5.22), and (5.25) we obtain (5.19).

6. Riemannian metric circles and other generalizations

It is reasonable to ask whether (1.9) holds for functions $\Phi$ which satisfy the cinematic curvature conditions but are not algebraic. An examination of the arguments above reveals that the only place where the algebraic properties of $\Phi$ are used is in Lemma 3.4, where we make use of the fact that the level sets of $\Phi(x, \cdot)$ (and of various functions obtained from $\Phi$) are algebraic curves, and in particular, any two such curves intersect $O(1)$ times.

One might hope that we could extend (1.9) to analytic $\Phi$ by approximating $\Phi$ by the first $\sim |\log \delta|$ terms of its Taylor expansion. Unfortunately, the bounds obtained above are more than superexponential in the degree of $\Phi$, so if we approximate $\Phi$ by a polynomial of degree $\sim |\log \delta|$ then the above proof yields maximal function bounds that are worse than the Kolasa–Wolff result (1.8).

Working through the proof of Lemma 3.4, we see that the proof requires us to control the number of times certain pairs of curves can intersect. For $x, \tilde{x} \in U_1, \omega \in \{ \pm 1 \}$, let
\begin{equation}
\gamma_{x, \tilde{x}, \omega, r} = \{ y : \Phi(x, y) + \omega \Phi(\tilde{x}, y) = r \}.
\end{equation}

We shall call such curves $\Phi$-conics.
Definition 6.1. We say that $\Phi$ has the \textit{bounded conic intersection property} if it satisfies the following requirements:

(i) If $\{x, \tilde{x}\} \neq \{x', \tilde{x}'\}$, then
\begin{equation}
\#(\gamma_{x, \tilde{x}, \omega, r} \cap \gamma_{x', \tilde{x}', \omega', r'}) \lesssim 1.
\end{equation}

(ii) All $\Phi$-circles $\Gamma$ and $\Phi$-conics $\gamma$ have $O(1)$ $y^{(1)}$-extremal points (defined below).

Definition 6.2. A \textit{$y^{(1)}$-extremal point} of a curve $\zeta$ is a point $y_0 \in \zeta$ such that $\zeta \cap V$ is contained in one of the closed half-spaces $\{y^{(1)} \geq y_0^{(1)}\}$ or $\{y^{(1)} \leq y_0^{(1)}\}$ for $V$ a sufficiently small open neighborhood of $y_0$.

Requirement (6.2) is the most difficult to satisfy, and it is the analogue of the Euclidean statement that distinct irreducible conic sections intersect in at most $O(1)$ places (actually 4).

If $\Phi$ satisfies the cinematic curvature hypotheses, it need not have the bounded conic intersection property. Indeed, consider the example
\begin{equation}
\Phi(x, y) = y^{(2)} + x^{(1)} y^{(1)} + x^{(2)} (y^{(1)})^2 + p(x, y).
\end{equation}

If $p(x, y) = 0$, the $\Phi$-conics $\gamma = \{y : \Phi((1, 0), y) + \Phi((-1, 0), y) = r\}$ and $\tilde{\gamma} = \{y : \Phi((0, 1), y) + \Phi((0, -1), y) = r\}$ are identical (both are simply the line $y^{(2)} = r$). Thus we can select $p$ to be a highly oscillatory $C^\infty$ perturbation which causes $\#(\gamma \cap \tilde{\gamma})$ to be arbitrarily large, independent of (say) the $C^3$-norm of $\Phi$ (we could choose some other reasonable norm on $\Phi$ and construct similar counter-examples). For example, we could choose
\begin{equation}
p(x, y) = C^{-1} \phi(x) \left( y^{(2)} - \exp \left[ -1/\|y^{(1)}\|^6 \right] \sin \left( \exp \left[ 1/\|y^{(1)}\|^2 \right] \right) \right)
\end{equation}
for $\phi(x)$ a $C^\infty$ function supported in a small neighborhood of $(1, 0)$. This choice of $\Phi$ satisfies the cinematic curvature hypothesis, since it satisfies (4.2) and (4.3) (provided we choose $C$ sufficiently large so the contributions from $p$ do not affect the calculations), but it does not satisfy (6.2). Of course, the $\Phi$ given in (6.3) may still satisfy (1.9), but a different proof would be needed.

Added 2/14/2012: Indeed, the new results from [16] show that the defining function $\Phi$ from (6.3) satisfies the bound (1.9), though of course $\Phi$ from (6.3) does not have the bounded conic intersection property.

While general $\Phi$ need not satisfy (6.2), we conjecture:

Conjecture 6.3. Let $\Phi(x, y) = \rho(x, y)$ for $\rho$ a Riemannian metric sufficiently close to Euclidean. Then $\Phi$ satisfies the bounded conic intersection property.

This would imply

Corollary 6.4 (conditional on Conjecture 6.3). Let $\Phi(x, y)$ be as in Conjecture 6.3. Then (1.9) holds for $M_\Phi$. 
Remark 6.5. Actually, we can still obtain Corollary 6.4 if we weaken Conjecture 6.3 to the following statement: If $\Phi(x, y) = \rho(x, y)$ for $\rho$ a Riemannian metric, define a $\delta$-generic $\Phi$-conic to be a curve $\gamma_{x, \tilde{x}, \omega, r}$ which is not contained in the $\delta$-neighborhood of any geodesic (this is a quantitative analogue of an (algebraic) conic section being irreducible). Then $\gamma_{x, \tilde{x}, \omega, r}$ admits a decomposition $\gamma_{x, \tilde{x}, \omega, r} = \bigcup_i \gamma^i_{x, \tilde{x}, \omega, r}$ into $\lesssim |\log \delta|^C$ connected components such that (6.2) is satisfied for any two components of any two $\Phi$-conics.

A. The cell decomposition

We shall give a brief sketch of the techniques developed by Chazelle et al. in [4] (see also [5] and [1] for a rigorous exposition closer to the one sketched here) on the method of vertical cell decompositions and random sampling.

Let $\mathcal{S} = \{S_1, \ldots, S_N\}$ be a collection of 2-dimensional semi-algebraic sets in $\mathbb{R}^3$ (for which we shall use the coordinates $(x, r) \in \mathbb{R}^2 \times \mathbb{R}$).

By subdividing each $S_i$ into a bounded number of pieces if necessary, we may assume that each set $S_i$ may be written in one of the following three forms:

- $S = \text{graph}(f)$, for $f : V \to \mathbb{R}$ a smooth algebraic function and $V \subset \mathbb{R}^2$ a (Euclidean) open semi-algebraic set. We shall call these sets “surface patches”.
- $S_i$ a semi-algebraic set with $\dim(S_i) = 2$ but $\dim(\pi_x(S_i)) = 1$. We shall call these sets “vertical manifolds.”
- $S_i$ a semi-algebraic set with $\dim(S_i) < 2$.

To keep our exposition brief, we shall ignore the latter two types of sets, since their presence is merely a technical annoyance that does not contribute significantly to the analysis of the decomposition. Thus we shall assume that the sets in $\mathcal{S}$ consist entirely of surface patches.

Definition A.1. For $S$ a surface patch, we shall define $\text{bdry}(S) = \overline{S} \setminus S$, where $\overline{S}$ denotes the closure of $S$ in the Euclidean (rather than Zariski) topology. Note that $\dim(\text{bdry}(S)) = 1$.

Definition A.2. A vertical line segment $L \subset \mathbb{R}^3$ is a connected 1-dimensional semi-algebraic set with the property that $\pi_x(L)$ is a point. If $(x_0, r_0) \in \mathbb{R}^3$, we say that the (connected) vertical line segment $L$ containing $(x_0, r_0)$ is maximal with respect to $S$ if $L$ meets no point of any surface in $\mathcal{S}$ except possibly at $(x_0, r_0)$, but any strictly larger line segment does.

If $\gamma \subset \mathbb{R}^3$ is a 1-dimensional semi-algebraic set (i.e. a union of segments of algebraic curves) which is not a union of vertical lines and isolated points, then if we erect a maximal line segment from every point of $\gamma$ we obtain a 2-dimensional semi-algebraic set $V_\gamma$ with $\pi_x(V_\gamma) = \pi_x(\gamma)$. We shall call this set the “maximal vertical wall above $\gamma$” (relative to $S$).

To construct the cell decomposition, erect a maximal vertical wall above $S \cap \tilde{S}$ for every pair of distinct $S, \tilde{S} \in \mathcal{S}$, and a maximal vertical wall above $\text{bdry}(S)$ for each $S \in \mathcal{S}$. If we consider $\mathbb{R}^3$ with the surfaces $S \in \mathcal{S}$ and the above maximal
vertical walls removed, then the remaining connected sets (which we shall call pre-cells) each have a unique “top” and “bottom” bounding surface, i.e. for each pre-cell \( \Omega \) there are unique \( S, \tilde{S} \in S \) such that any maximal line containing \((x, r) \in \Omega\) terminates at points in \( S \) and \( \tilde{S} \). Thus at this point, each pre-cell is a “cylindrical algebraic set,” i.e., it is of the form

\[
\Omega = \{(x, r) : x \in V_\Omega, f_{1,\Omega}(x) < r < f_{2,\Omega}\}
\]

for \( V_\Omega \subset \mathbb{R}^2 \) an open, semi-algebraic set and algebraic functions \( f_{1,\Omega}, f_{2,\Omega} \).

Now, \( \text{bdry}(V_\Omega) \) is a 1-dimensional semi-algebraic set, and thus it can be written uniquely as an almost disjoint finite union of segments of irreducible algebraic curves such that if any two segments share a boundary point then their defining polynomials are distinct (and thus neither defining polynomial divides the other). We will call the boundaries of these segments the vertices of \( V_\Omega \). Now, for each vertex \( x_0 \in V_\Omega \), erect the wall

\[
W_{x_0,\Omega} = \{(x, r) \in \Omega : x^{(1)} = x_0^{(1)}\}
\]

Finally, if \( \gamma \) is a 1-dimensional semi-algebraic set, then we say that \( x_0 \in \Gamma \) is a \( x^{(1)} \)-extremal point if there exists an open neighborhood \( U \) of \( x_0 \) and an irreducible algebraic curve \( \gamma' \) containing \( \gamma \cap U \) such that \( \gamma' \cap U \) is contained in one of the closed half planes \( \{x : x^{(1)} \geq x_0^{(1)}\} \) or \( \{x : x^{(1)} \leq x_0^{(1)}\} \) (see Figure 1).

**Figure 1.** Examples of extremal and non-extremal points of a semi-algebraic curve.

**Remark A.3.** This definition of a \( x^{(1)} \)-extremal point is consistent with the definition given in Section 6 (Definition 6.2) for \( \Phi \)-conics when \( \Phi(x, y) \) is a smooth algebraic function. The wording of the above definition differs from that of Definition 6.2 since in Definition 6.2 we do not assume that the defining function is algebraic, and thus there is no notion analogous to the Zariski closure of a semi-algebraic set or of an irreducible component of an algebraic set.

For each extremal point \( x_0 \in V_\Omega \), erect the vertical wall \( W_{x_0,\Omega} \). Once this has been done, a vertical wall will have been erected in \( \Omega \) above each of the dashed lines in \( V_\Omega \) in Figure 2. We also need to add some additional vertical walls \( W_{x_0,\Omega} \).
with $x_0$ the endpoint of certain line segments (since the irreducible algebraic curve that contains a line segment is of course a line, which (provided it is not parallel to the $x^{(2)}$-axis) does not have any $x^{(1)}$-extreme points), but in the interest of brevity we shall gloss over this point (we can also ensure that line segments never occur by applying a slight perturbation at an earlier stage of the decomposition).

Once these vertical walls have been erected for each cell $\Omega$, the resulting arrangement of surfaces partitions $\mathbb{R}^3$ into topologically trivial open sets (cells). This partition has the following properties:

(i) Each cell is a semi-algebraic set defined by at most 6 algebraic surfaces.

(ii) For each cell $\Omega$, there is a collection of at most 6 surfaces $S_1, \ldots, S_6 \in \mathcal{S}$ such that if the above cell decomposition algorithm were applied to $S' = \{S_1, \ldots, S_6\}$, then $\Omega$ would be one of the resulting cells in the decomposition.

(iii) There are $\lesssim N^3 \log N$ cells.

Properties (i) and (ii) are immediate from the above cell decomposition algorithm: each cell $\Omega$ is contained in a unique pre-cell $\Omega'$. The top and bottom of $\Omega$ are the same algebraic surfaces $S, \tilde{S}$ as the top and bottom of $\Omega'$. The “front” and “back” walls of $\Omega$ (if they exist) are segments of the vertical wall raised above curves $\gamma, \tilde{\gamma}$ which were obtained by intersecting respectively $S$ and $\tilde{S}$ with two other surfaces $S', \tilde{S}' \in \mathcal{S}$, and the “right” and “left” walls of $\Omega$ (if they exist) are walls of the form $W_{x_0, \Omega}$ where $x_0$ is a point of intersection of $\gamma_1$ and $\gamma_2$, where $\gamma_1$ is a section of $S \cap S'$ or $\tilde{S} \cap \tilde{S}'$, and $\gamma_2$ is a section of $S \cap S_1$ or $\tilde{S} \cap \tilde{S}_1$ for some $S_1$ or $\tilde{S}_1 \in \mathcal{S}$.

The analysis required to obtain (iii) is somewhat lengthy, but the key idea is as follows. The main step in obtaining property (iii) is to bound the number of vertices in the sets $V_\Omega$, since a bound on the number of vertices leads to a bound on the number of vertical walls $W_{x_0, \Omega}$ added to the arrangement (the contribution from the vertical walls from $x^{(1)}$-extremal points is negligible). These vertices arise
when the algebraic curves defining $\partial V_\Omega$ intersect. By Bézout’s theorem, any two algebraic curves intersect in at most $O(1)$ places (since $\Phi$ is of bounded degree, all of the algebraic curves appearing in the cell decomposition are also of bounded degree). This fact allows us to use the theory of Davenport–Schinzel sequences to control the total number of intersections between the algebraic curve segments that define the boundaries of the cells (and thus the total number of vertices occurring in the sets $V_\Omega$ as $\Omega$ ranges over the cells in the decomposition).

Property (ii) of the cell decomposition allows us to use a random sampling argument of the type discussed in [5] to obtain Lemma 3.4. We shall give a brief sketch of this lemma here. Let $\mathcal{S}$ be a collection of 2-dimensional semi-algebraic surfaces with $\# \mathcal{S} = n$. Randomly select a subset $\mathcal{D} \subset \mathcal{S}$ with $\# \mathcal{D} = N < C^{-1}n$ (the requirement $N < C^{-1}n$ allows us to gloss over the distinction between selecting curves from $\mathcal{S}$ with and without replacement, since the probability of the same curve being selected twice is low). Apply the above cell decomposition algorithm to the collection $\mathcal{D}$. For each resulting cell $\Omega$ in the decomposition, let $Z(\Omega) = \# \{ S \in \mathcal{S} : S \cap \Omega \neq \emptyset \}$. Then,

$$P(Z(\Omega) \geq \lambda \mid \Omega \cap S = \emptyset \text{ for all } S \in \mathcal{D}) \leq \left(1 - \frac{\lambda}{n}\right)^{N}.$$  \\
If we set $\lambda = C \frac{n \log n}{N}$, then the right hand side of (A.1) is $\lesssim n^{-C}$. Thus since our vertical algebraic decomposition gives us an injection from $\mathcal{D}^6$ into the collection of all cells arising from the decomposition of the collection of surfaces $\mathcal{D}$, and since each cell in the resulting decomposition does not intersect any of the surfaces in $\mathcal{D}$ (since the cells are subsets of $\mathbb{R}^3 \setminus \bigcup_{S \in \mathcal{D}} S$), the probability that even a single cell meets more than $\lambda = C \frac{n \log n}{N}$ surfaces is at most $C' n^{6-C}$, which we can make arbitrarily small by choosing $C$ sufficiently large.

\section*{B. Real algebraic geometry}

In this appendix we shall briefly review a few definitions and theorems from real algebraic geometry. Throughout our discussion, the base field shall be $\mathbb{R}$ and all polynomials shall be assumed to have real coefficients. Unless otherwise noted, all open sets shall be assumed to be open in the Euclidean topology. Many of the results discussed below are applicable to any real field but we shall not pursue this here. Further details on the material reviewed below can be found in [3], [2], and [9] (see [11] for an English summary of the key results we need from [9]).

\textbf{Definition B.1.} A set $S \subset \mathbb{R}^n$ is \textit{semi-algebraic} if

$$S = \bigcup_{i=1}^{n} \{ x : f_{i,1}(x) = 0, \ldots f_{i,\ell_i}(x) = 0, \quad g_{i,1}(x) > 0, \ldots, g_{i,m_i}(x) > 0 \} ,$$

where $\{f_{i,j}\}$ and $\{g_{i,j}\}$ are collections of polynomials.
**Definition B.2.** The complexity of a semi-algebraic set is defined as

\[(B.2) \min \left( \sum_{i,j} \deg f_{i,j} + \sum_{i,j} \deg g_{i,j} \right), \]

where the minimum is taken over all representations of \(S\) of the form (B.1).

**Remark B.3.** This definition of complexity is not standard. In the body of the paper we refer to sets of “bounded complexity.” This means that the complexity of the semi-algebraic set is bounded by a number that depends only on the defining function \(\Phi\) from (1.9).

**Definition B.4.** A function \(f: \mathbb{R}^n \to \mathbb{R}^m\) is semi-algebraic if its graph is a semi-algebraic set. The complexity of a semi-algebraic function is the complexity of its graph.

**Theorem B.5** (Tarski–Seidenberg). Let \(S \subset \mathbb{R}^n\) be semi-algebraic. Then

\[\pi(x_1, \ldots, x_{n-1})(S) \subset \mathbb{R}^{n-1}\]

is semi-algebraic, and the complexity of \(\pi(x_1, \ldots, x_{n-1})(S)\) is controlled by the complexity of \(S\).

**Definition B.6.** Let \(S \subset \mathbb{R}^n\) be a semi-algebraic set. We define

\[(B.3) \quad \mathcal{I}(S) = \{ f \in \mathbb{R}[X_1, \ldots, X_n] : f|_S \equiv 0 \}. \]

\(\mathcal{I}(S)\) is an ideal in \(\mathbb{R}[X_1, \ldots, X_n]\).

**Definition B.7.** For an ideal \(\mathcal{I}\) in \(\mathbb{R}[X_1, \ldots, X_n]\), we define

\[(B.4) \quad \mathcal{Z}(\mathcal{I}) = \{ (x_1, \ldots, x_n) \in \mathbb{R}^n : f(x_1, \ldots, x_n) = 0 \text{ for all } f \in \mathcal{I} \}, \]

so in particular, \(S \subset \mathcal{Z}(\mathcal{I}(S))\).

**Definition B.8.** Let \(S\) be a semi-algebraic set. We define

\[\mathcal{P}(S) = \mathbb{R}[X_1, \ldots, X_n]/\mathcal{I}(S).\]

Then the dimension of \(S\) is given by

\[\dim(S) = \dim(\mathcal{P}(S)),\]

the maximal length of a chain of prime ideals in the ring \(\mathcal{P}(S)\) (see e.g. [6]).

**Proposition B.9.** Let \(S\) be a semi-algebraic set. Then \(S\) has the same dimension as its closure in the real Zariski topology, i.e.,

\[\dim(S) = \dim(\mathcal{Z}(\mathcal{I}(S))),\]

and the latter set is algebraic.
Proposition B.10. Let \( f(x, x_{n+1}) \) be a polynomial in \( n + 1 \) variables. Then there exists a partition of \( \mathbb{R}^n \) into semi-algebraic sets \( A_1, \ldots, A_m \) and for each \( i = 1, \ldots, m \) a finite number of semi-algebraic functions \( \xi_{i,1}, \ldots, \xi_{i,\ell_i} : A_i \to \mathbb{R} \) such that

(i) For each \( x \in A_i \) such that \( f(x, \cdot) \) is not identically 0,

\[
\{ \xi_{i,1}(x), \ldots, \xi_{i,\ell_i}(x) \} = \{ x_{n+1} : f(x, x_{n+1}) = 0 \}.
\]

(ii)

\[
\text{graph}(\xi_{i,j}) \subset \{ f = 0 \}.
\]

The complexities of the \( A_i \) and \( \xi_{i,j} \) depend only on the complexity of \( f \).

Corollary B.11. Let \( S \subset \mathbb{R}^{n+1} \) be an algebraic set. Then we can write

\[
S = \bigcup_{i=1}^{n} S_i \cup \bigcup_{i=1}^{m} T_i,
\]

with \( S_i = \text{graph}(f_i|_{A_i}) \) for \( f_i \), a smooth algebraic function and \( A_i \subset \mathbb{R}^n \) an open semi-algebraic set, and \( \dim \pi(x_1, \ldots, x_n)(T_i) < \dim S \). The complexities of the \( f_i, A_i, \) and \( T_i \) depend only on the complexity of \( S \).

Remark B.12. In addition to Proposition B.10, Corollary B.11 relies on the fact that the set of singular points of a semi-algebraic set is itself a semi-algebraic set of strictly lower dimension (see Chapter 2 of [3] for a complete discussion of these ideas).

Proposition B.13. Let \( S = \bigcup_{i=1}^{n} S_i \) with \( S_i \) a semi-algebraic set homeomorphic to \( [0,1]^{d_i} \). Then \( \dim(S) = \max\{d_1, \ldots, d_n\} \).

Proposition B.14. Let \( S \) be a semi-algebraic set that is also a smooth manifold. Then \( \dim(S) \) equals the dimension of \( S \) as a smooth manifold.
