Finite simple groups of Lie type as expanders

Dedicated to the memory of Beth Samuels who is deeply missed

Received April 16, 2009 and in revised form December 19, 2009

Abstract. We prove that all finite simple groups of Lie type, with the exception of the Suzuki groups, can be made into a family of expanders in a uniform way. This confirms a conjecture of Babai, Kantor and Lubotzky from 1989, which has already been proved by Kassabov for sufficiently large rank. The bounded rank case is deduced here from a uniform result for $\text{SL}_2$ which is obtained by combining results of Selberg and Drinfeld via an explicit construction of Ramanujan graphs by Lubotzky, Samuels and Vishne.

1. Introduction

A finite $k$-regular graph $X$, $k \in \mathbb{N}$, is called an $\varepsilon$-expander ($0 < \varepsilon \in \mathbb{R}$) if for every subset $A$ of vertices of $X$ with $|A| \leq \frac{1}{2}|X|$, we have $|\partial A| \geq \varepsilon |A|$ where $\partial A = \{y \in X \mid \text{dist}(y, A) = 1\}$.

The main goal of this paper is to prove:

Theorem 1.1. There exist $k \in \mathbb{N}$ and $0 < \varepsilon \in \mathbb{R}$ such that if $G$ is a finite simple group of Lie type, but not a Suzuki group, then $G$ has a set $S$ of $k$ generators for which the Cayley graph $\text{Cay}(G; S)$ is an $\varepsilon$-expander.

By abuse of language, we will say that these groups are uniform expanders.

Theorem 1.1 is new only for groups of small Lie rank: in [K1], Kassabov proved that the groups

$$[\text{SL}_n(q) \mid 3 \leq n \in \mathbb{N}, q \text{ a prime power}]$$

are uniform expanders. Nikolov [N] proved that every classical group is a bounded product of $\text{SL}_n(q)$’s (with $n = 2$ possible, but the proof shows that if the Lie rank is sufficiently high, say $\geq 14$, one can use $\text{SL}_n(q)$ with $n \geq 3$). Bounded products of uniform expanders are uniform expanders (see Corollary 2.2 below). Thus together, their results cover all classical groups of high rank. So, our theorem is new for classical groups of small ranks as well as for the families of exceptional groups of Lie type.

Theorem 1.1 gives the last step of the result conjectured in [BKL] and announced in [KLN]:

A. Lubotzky: Institute of Mathematics, Hebrew University, Jerusalem, 91904 Israel; e-mail: alexlub@math.huji.ac.il
Theorem 1.2 ([KLN]). All non-abelian finite simple groups, with the possible exception of the Suzuki groups, are uniform expanders.

By the classification of the finite simple groups, Theorem 1.1 covers all the simple groups except finitely many sporadic groups (for which the theorem is trivial) and the alternating groups. The fact that Theorem 1.2 holds for the alternating and the symmetric groups is a remarkable result of Kassabov [K2].

The main new family covered by our method is \( \{ \text{PSL}_2(q) \mid q \text{ a prime power} \} \). Unlike the results mentioned previously ([K1, K2]) whose proofs used ingenious, but relatively elementary methods, the proof for \( \text{PSL}_2(q) \) will use some deep results from the theory of automorphic forms. In particular, it will appeal to Selberg’s \( \lambda_1 \geq 3/16 \) Theorem ([Se], see also [Lu, Chap. 4]) and Drinfeld’s solution to the characteristic \( p \) Ramanujan conjecture ([Dr]).

For its importance, let us single it out as:

**Theorem 1.3.** The groups \( \{ \text{PSL}_2(q) \mid q \text{ a prime power} \} \) form a family of uniform expanders.

Let us mention right away that Theorem 1.3 was known before for several subfamilies, e.g. for \( \{ \text{PSL}_2(p) \mid p \text{ prime} \} \) (see [Lu, Chap. 4]) or \( \{ \text{PSL}_2(p^r) \mid p \text{ a fixed prime and } r \in \mathbb{N} \} \) ([Mo]). The main novelty is to make them expanders uniformly for all \( p \) and all \( r \). To this end we will use the representation-theoretic reformulation of the expanding property (see §2) as well as the new explicit constructions of Ramanujan graphs in [LSV2] as special cases of Ramanujan complexes. We stress that the explicit construction there is crucial for our method and not only the theoretical construction of [LSV1]. This will be shown in §3.

The case of \( \text{SL}_2 \) is a key step for the other groups of Lie type: a result of Hadad ([H1], which is heavily influenced by Kassabov [K1]) enables one to deduce \( \text{SL}_n \) (\( n \geq 2 \)) from \( \text{SL}_2 \). Then in §4, we use a model-theoretic argument to show that simple groups of Lie type of bounded rank (including the exceptional families except the Suzuki groups) are bounded products of \( \text{SL}_2 \)’s. Together with Nikolov’s result mentioned above, Theorem 1.1 is then fully deduced.

The Suzuki groups have to be excluded as they do not contain a copy of \( (P) \text{SL}_2(q) \) for any \( q \), but we believe that Theorem 1.2 holds for them as well. (**Added in proof:** Recently Breuillard, Green and Tao solved this case (“Suzuki groups as expanders”, arXiv:1005.0782) by a completely different method. So the Babai–Kantor–Lubotzky conjecture is now fully proved.)

2. **Representation-theoretic reformulation**

It is well known (cf. [Lu, Chap. 4]) that expanding properties of Cayley graphs \( \text{Cay}(G; S) \) can be reformulated in the language of the representation theory of \( G \). For our purpose we will also need to consider cases for which \( S \) is not of bounded size, in spite of the fact that our final result deals with \( S \) bounded. We therefore need a small extension of some standard results, for which we need some notation:
The normalized adjacency matrix of a connected $k$-regular graph $X$ is defined to be
$$\Delta = (1/k)A$$ where $A$ is the adjacency matrix of $X$. The eigenvalues of $\Delta$ are in the
interval $[-1, 1]$. The largest eigenvalue in absolute value in $(-1, 1)$ is denoted $\lambda(X)$.

For a group $G$, a set $S$ of generators and $\alpha > 0$, we denote by $I(\alpha, G, S)$ the statement:

For every unitary representation $(V, \rho)$ of $G$, every $v \in V$ and every $0 < \delta \in \mathbb{R}$, if
$$\|\rho(s)v - v\| < \delta$$ for each $s \in S$, then $$\|\rho(g)v - v\| < \alpha\delta$$ for every $g \in G$, (i.e., a vector $v$
which is “$S$-almost invariant” is also “$G$-almost invariant”.)

Note that the statement $I(\alpha, G, S)$ refers to all the unitary representations of $G$,
whether they have invariant vectors or not.

**Proposition 2.1.**

(i) For every $\alpha > 0$ there is $\varepsilon = \varepsilon(\alpha) > 0$ such that if $G$ is a finite
group, $S$ a set of generators, and $I(\alpha, G, S)$ holds, then Cay$(G; S)$ is an $\varepsilon$-expander.

(ii) For every $\eta > 0$, there exists $\alpha = \alpha(\eta)$ such that if $G$ is a finite group, $S$ a set of
generators, and $\lambda$(Cay$(G; S)) < 1 - \eta$, then $I(\alpha, G, S)$ holds.

(iii) If $k = |S|$ is bounded then the implication in (i) can be reversed. (So Cay$(G; S)$ is an
expander if every “$S$-almost invariant” vector is also “$G$-almost invariant”.)

**Proof.** We note first that property $I(\alpha, G, S)$ implies that there exists $\beta = \beta(\alpha) > 0$
such that for every unitary representation $(V, \rho)$ of $G$ without a non-zero invariant vector, and
every $v \in V$ with $\|v\| = 1$, $\|\rho(s)v - v\| \geq \beta$ for some $s \in S$. Indeed, take $\beta < 1/(2\alpha)$ and
so if $\|\rho(s)v - v\| < \beta$ for every $s \in S$, then $I(\alpha, G, S)$ implies that $\|\rho(g)v - v\| < 1/2$
for every $g \in G$. This implies that $\overline{v} = \{1/|G|\sum_{g \in G} \rho(g)v\}$, which is clearly a
$G$-invariant vector, is non-zero since $\|\overline{v} - v\| < 1/2$. This contradicts our assumption that $V$ does
not contain an invariant vector.

Altogether, $I(\alpha, G, S)$ implies the usual “property (T)” formulation and so the standard
proof of Proposition 3.3.1 of [Lu] applies to show that Cay$(G; S)$ is an $\varepsilon$-expander
for some $\varepsilon = \varepsilon(\beta(\alpha))$. This proves (i). The proof of (ii) is also a small modification of the
standard equivalences (see [Lu, Theorem 4.3.2]): as is well known, a normalized eigen-
value gap (i.e. $\lambda$(Cay$(G; S)) = 1 - \eta$) implies “average expanding”, i.e. if $(V, \rho)$ does
not contain an invariant vector, then
$$\frac{1}{|S|} \sum_{s \in S} \|\rho(s)v - v\| \geq \eta'\|v\|$$

(see $\eta'$ depends only on $\eta$). Note that when $S$ is unbounded, this is a stronger property
than “expanding” which gives that for one $s \in S$, $\|\rho(s)v - v\| \geq \eta''\|v\|$ (for $\eta'' = \eta''(\eta)$).

Now, assume $(V, \rho)$ is an arbitrary unitary representation of $G$ and $v \in V$, of norm one,
is $\delta$-invariant under $S$ for some $\delta < \eta'$. Then $(*)$ implies that a large portion of $v$ is in the
space $V^G$ of $G$-fixed points. Hence $v$ is $G$-almost invariant as needed.

Part (iii) is just the standard equivalences as in [Lu, Theorem 4.3.2].

An easy corollary of Proposition 2.1 is that “bounded products of expanders are
expanders”, or in a precise form:

**Corollary 2.2.** Let $G$ be a finite group and $G_i, i = 1, \ldots, \ell$, a family of subgroups of $G$,
each coming with a set of generators $S_i \subseteq G_i$, $i = 1, \ldots, \ell$, with $|S_i| \leq r$. Assume
\[ G = G_1 \cdots G_\ell, \text{ i.e., every } g \in G \text{ can be written as } g = g_1 \cdots g_\ell \text{ with } g_i \in G_i. \] If all \( \text{Cay}(G_i; S_i) \) are \( \delta \)-expanders, then \( \text{Cay}(G; S) \) is an \( \varepsilon \)-expander for \( S = \bigcup_{i=1}^\ell S_i \) and \( \varepsilon \) which depends only on \( \delta \) and \( \ell \).

**Proof.** If \((V, \rho)\) is a unitary representation of \( G \), and \( v \in V \) is a vector which is almost invariant under \( S \), then it is almost invariant under each of the subgroups \( G_i \) (by 2.1(iii)), and as \( G \) is their product, it is also almost invariant under \( G \). Now use 2.1(i) to deduce the corollary. \( \Box \)

Let us mention here another fact that will be used freely later. The following proposition is a special case of a more general result in [H2]:

**Proposition 2.3.** Let \( \{G_i\}_{i \in I} \) be a family of perfect finite groups (i.e. \( [G_i, G_i] = G_i \)) with sets \( S_i \) of generators. Assume \( \pi_i : \tilde{G}_i \to G_i \) is a central perfect cover of \( G_i \) and \( \tilde{S}_i \subset \tilde{G}_i \) a subset for which \( \pi(\tilde{S}_i) = S_i \) and \( |\tilde{S}_i| = S_i \). If \( \text{Cay}(G_i; S_i) \) are uniform expanders, then so are \( \text{Cay}(\tilde{G}_i; \tilde{S}_i) \).

The proposition shows that proving uniform expanding for finite simple groups or for their central extensions is the same problem. So groups of the form \( \text{PSL}_d(q) \) are expanders iff \( \text{SL}_d(q) \) are.

### 3. \text{SL}_2: Proof of Theorem 1.3

The goal of this section is to show that all the groups \( \{\text{SL}_2(q) \mid q \text{ a prime power} \} \) (and hence also \( \text{PSL}_2(q) \)) are uniform expanders. Let us recall

**Theorem 3.1.** The Cayley graphs

\[
\text{Cay}\left(\text{PSL}_2(p); \left\{ A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, B = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \right\}\right)
\]

for \( p \) prime, are 3-regular uniform expanders.

For a proof, see [Lu, Theorem 4.4.2]. The proof uses the Selberg Theorem \( \lambda_1(\Gamma(m) \backslash \mathbb{H}^2) \geq 3/16 \)—giving a bound on the eigenvalues of the Laplace–Beltrami operator of the congruence modular surfaces. For a new method see [BG].

Another preliminary result needed is:

**Theorem 3.2.** (a) For a fixed prime \( p \), each of the groups \( \text{PSL}_2(p^k), k \in \mathbb{N} \) and \( p^k > 17 \), has a symmetric subset \( S_p \) of \( p + 1 \) generators for which the Cayley graph \( X = \text{Cay}(\text{SL}_2(p^k); S_p) \) is a \((p + 1)\)-regular Ramanujan graph, i.e. \( \lambda(X) \leq 2\sqrt{p/(p + 1)} \).

(b) The set of generators \( S_p \) in part (a) can be chosen to be of the form \( \{h^{-1} Ch \mid h \in H\} \), where \( C \) is some element of \( \text{SL}_2(p^k) \) and \( H \) is a fixed non-split torus of \( \text{PGL}_2(p) \).

(The proof will give a more detailed description of \( S_p \).)
Before proving Theorem 3.2, let us mention that part (a) has already been proven by Morgenstern [Mo], but the specific form of the generators as in (b) is crucial for our needs. We therefore appeal to [LSV2] instead of [Mo]. We recall the construction there: Let \( \mathbb{F}_q \) be the field of order \( q \) (a prime power), \( \mathbb{F}_q^d \) the extension of dimension \( d \), and \( \phi \) a generator of the Galois group \( \text{Gal}(\mathbb{F}_q^d/\mathbb{F}_q) \). Fix a basis \( \{\xi_0, \ldots, \xi_{d-1}\} \) for \( \mathbb{F}_q^d \) over \( \mathbb{F}_q \) where \( \xi_i = \phi^i(\xi_0) \). Extend \( \phi \) to an automorphism of the function field \( k = \mathbb{F}_q(y) \) by setting \( \phi(y) = y \); the fixed subfield is \( k = \mathbb{F}_q(y) \), of codimension \( d \).

Following the notation in [LSV2], we will denote by \( R_T \) the ring \( \mathbb{F}_q[y, \frac{1}{1+y}] \) and for every commutative \( RT \)-algebra \( S \) (with unit), we denote by \( y \) the element \( y \cdot 1 \in S \). For such \( S \) one defines an \( S \)-algebra \( A(S) = \bigoplus_{d=0}^{q} S\xi_i z^d \) with the relations \( z\xi_i = \phi(\xi_i)z \) and \( z^d = 1 + y \). Let \( R = \mathbb{F}_q[y, \frac{1}{1+y}] \subset k \) and denote \( b = 1 + z^{-1} \in A(R) \). For every \( u \in \mathbb{F}_y^\times \subset A(R)^* \), we denote \( b_u = ubu^{-1} \). As \( \mathbb{F}_q^* \) is in the center of \( A(R) \), \( b_u \) depends on the coset of \( u \) in \( \mathbb{F}_q^*/\mathbb{F}_q^* \). This gives \( (q^d - 1)/(q - 1) \) elements \( \{b_u \mid u \in \mathbb{F}_q^*/\mathbb{F}_q^* \} \) of \( A(R)^* \). The subgroup of \( A(R)^* \) generated by the \( b_u \)'s is denoted by \( \tilde{\Gamma} \) and its image in \( A(R)/R^* \) by \( \Gamma = \Gamma_{d,q} \). For every ideal \( I \triangleleft R \), we get a map

\[
\pi_I : A(R)^*/R^* \to A(R/I)^*/(R/I)^*.
\]

The intersection \( \Gamma \cap \text{Ker} \pi_I \) is denoted \( \Gamma(I) \).

Theorem 6.2 of [LSV2] says:

**Theorem 3.3.** For every \( d \geq 2 \) and every \( 0 \neq I \triangleleft R \), the Cayley complex of \( \Gamma/\Gamma(I) \) is a Ramanujan complex.

The reader is referred to [LSV1] and [LSV2] for the precise definition of Ramanujan complexes and for the precise complex structure of \( \Gamma/\Gamma(I) \). What is relevant for us here is that this gives a spectral gap on the Cayley graph of \( \Gamma/\Gamma(I) \) with respect to the \((q^d - 1)/(q - 1)\) generators \( S = \{b_u \mid u \in \mathbb{F}_q^*/\mathbb{F}_q^* \} \).

When \( d = 2 \), \( S \) is a symmetric set of generators of \( \Gamma \) and so Cay\((\Gamma/\Gamma(I); S)\) is a \( k = (q + 1) \)-regular graph. When \( d \geq 3 \), \( S \cap S^{-1} = \emptyset \) and Cay\((\Gamma/\Gamma(I); S)\) is a \( k = \frac{2(q^d - 1)}{q - 1} \)-regular graph. Let \( A \) be its adjacency matrix and \( \Delta = (1/k)A \) the normalized adjacency matrix. Theorem 3.3 implies:

**Corollary 3.4.** Denote by \( \mu_d \) the roots of unity in \( \mathbb{C} \) of degree \( d \), and let \( E_d = \{(y + \bar{y})/2 \mid y \in \mu_d \} \). Let \( \lambda \) be an eigenvalue of \( \Delta \). Then either \( \lambda \in E_d \) or

\[
|\lambda| \leq \frac{dq^{(d-1)/2}}{(q^d - 1)/(q - 1)}.
\]

**Remark 3.5.** Note that when \( d = 2 \), we have \( k = |S| = q + 1 \), \( E_d = \{\pm 1\} \) and Corollary 3.4 states that Cay\((\Gamma/\Gamma(I); S)\) is a Ramanujan graph. The proof of this bound for \( d = 2 \) requires Drinfeld’s theorem (the Ramanujan conjecture for \( GL_2 \) over positive characteristic fields) and for \( d \geq 3 \) is based on Lafforgue’s work [La]. It also requires the Jacquet–Langlands correspondence in positive characteristic (while this correspondence is not fully proved in the literature for \( d \geq 3 \), we use it here only for \( d = 2 \), which is
fully proved—see [LSV1, Remark 1.6]). We also mention that for $d \geq 3$, quantitative estimates on Kazhdan’s property (T) for $\text{PGL}_d(\mathbb{F}_q((y)))$ can give a weaker estimate such as: either $\lambda \in E_d$ or

$$\lambda \leq \frac{1}{\sqrt{q}} + o(1) \leq \frac{19}{20},$$

which is valid for every $d$ and $q$. But the case of $d = 2$ needs deep results from the theory of automorphic forms.

**Remark 3.6.** The description above of the results from [LSV2] brings only what is relevant to this paper. The bigger picture is as follows: The group $A(R)^* / R^*$ is a discrete cocompact lattice in $A(\mathbb{F}_q((y)))^*/\mathbb{F}_q((y))^*$. The latter is isomorphic to $H = \text{PGL}_d(\mathbb{F}_q((y)))$ and it acts on its Bruhat–Tits building $\mathbb{B}$. The element $b \in H$ takes the initial point of the building (the vertex $x_0$ corresponding to the lattice $\mathbb{F}_q[[y]]^d$) to a vertex $x_1$ at distance 1 from it, where the color of the edge $(x_0, x_1)$ is also one (so $x_1$ corresponds to an $\mathbb{F}_q[[y]]$-module of index $q$). The group $\mathbb{F}_q^*/\mathbb{F}_q^*$ acts transitively on these $(q^d - 1)/(q - 1)$ neighbors of $x_0$ of this type and the group $\Gamma$ generated by the $b_n$’s acts simply transitively on the vertices of $\mathbb{B}$—a result which goes back to Cartwright and Steger [CS]. For $b_0 \in S$, $b_n^{-1}$ takes $x_0$ to a neighboring vertex of $x_0$ where the edge is of color $d - 1$. When $d = 2$, we have $d - 1 = 1$, $S$ is a symmetric set of size $q + 1$ and Corollary 3.4 says that $\text{Cay}(\Gamma, \Gamma/(I); S)$ is a Ramanujan graph. For $d \geq 3$, $S \cap S^{-1} = \emptyset$ and $\text{Cay}(\Gamma, \Gamma/(I); S)$ is a regular graph of degree $2|S| = 2(q^d - 1)/(q - 1)$. The Ramanujan complex $\Gamma/(I)$ is in fact isomorphic to the quotient $\Gamma/(I)\mathbb{B}$ of the Bruhat–Tits building. On the building $\mathbb{B}$ (and on its quotients $\Gamma/(I)\mathbb{B}$) we have an action of $d - 1$ Hecke operators $A_1, \ldots, A_{d-1}$ and the Ramanujan property gives bounds on their eigenvalues. For $d \geq 3$, $A_1 + A_{d-1}$ is nothing other than the adjacency operator of the Cayley graph of $\Gamma/(I)$ with generators $\text{SUS}^{-1}$, and for $d = 2$, $A_1 = A_{d-1}$ and $A_1$ is the adjacency operator.

The structure of the quotient group $\Gamma/(I)$ is analyzed in [LSV2]; if $I$ is a prime ideal of $R$ with $R/I \simeq \mathbb{F}_q$, then $\Gamma/(I)$ is isomorphic to a subgroup of $\text{PGL}_d(q^e)$ containing $\text{PSL}_d(q^e)$. Theorem 7.1 of [LSV2] gives a more precise description, showing that essentially all subgroups between $\text{PSL}_d(q^e)$ and $\text{PGL}_d(q^e)$ can be obtained, if $I$ is chosen properly. The image of $S$ in $\text{PGL}_d(q^e)$, which we also denote by $S$, is composed of one element $C$, the image of $b$ in the notation above, and the conjugates of $C$ by the non-split tori in $\text{PGL}_d(q^e)$ of order $(q^d - 1)/(q - 1)$.

Note that $\text{PGL}_d(q^e)/\text{PSL}_d(q^e)$ is a cyclic group and the image of $S$ there is a single element—the image of $C$, since all the other elements of $S$ are conjugates of $C$. The eigenvalues in $E_d$ above may appear as “lifts” of the eigenvalues of the cyclic group generated by $C$ (which is a subgroup of $\text{PGL}_d(q^e)/\text{PSL}_d(q^e)$ and a quotient of $\Gamma/(I)$) whose order divides $d$. These eigenvalues will be called the **trivial eigenvalues** of $\text{Cay}(\Gamma/(I); S)$ and they are in the subset $E_d$ defined in Corollary 3.4. If the image of $\Gamma$ in $\text{PGL}_d(q^e)$ is only $\text{PSL}_d(q^e)$, then 1 is the only trivial eigenvalue of $\Delta$ and all the others satisfy the bound of Corollary 3.4.
For $d$ large the issue of which subgroup of $\text{PGL}_2(q^e)$ is obtained is somewhat delicate. For $d = 2$, which is what is needed here for the proof of Theorem 3.2, Theorem 7.1 of [LSV2] ensures that for $p^e > 17$, $\text{PSL}_2(p^e)$ can be obtained if $I$ is chosen properly. Thus $\text{Cay}(\text{PSL}_2(p^e); S)$ is a $(p+1)$-regular Ramanujan graph. It is, therefore, also an $\epsilon$-expander by Proposition 2.1(ii), but with an unbounded number of generators when $p$ goes to infinity.

We now show that this is true also with a bounded number of generators. An explicit form of Theorem 1.3 is:

**Theorem 3.7.** The Cayley graphs $\text{Cay}(\text{PSL}_2(\ell); \{A, B, C, C'\})$, when $\ell = p^e$ is any prime power, are uniform expanders. (Here $A = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, $C$ is as in the description above when $d = 2$ and $q = p$, and $C'$ will be described in the proof.)

**Proof.** Let $C$ be as described above (with $d = 2$ and $q = p$ a prime). The image of $S$ in $\text{PSL}_2(p^e)$, as described above, is the set of conjugates of $C$ under the action of the non-split torus $T$ of $\text{PGL}_2(p)$ which is isomorphic to $\mathbb{F}_p^*/\mathbb{F}_p^*$ and of order $p + 1$. Denote by $T_1 = T \cap \text{PSL}_2(p)$ a subgroup of index at most 2 in $T$ (in fact of index 2, unless $p = 2$). Let $C$ and $C'$ be two representatives of the orbits of $S$, under conjugation by $T_1$: $C$ as before and $C'$ a representative of the other orbit (if any).

We can now prove the theorem by using Proposition 2.1. Let $(V, \rho)$ be a unitary representation of $\text{PSL}_2(\ell)$, with an $\{A, B, C, C'\}$-almost invariant vector $v$. Restrict the representation $\rho$ to the subgroup $\text{PSL}_2(p)$. By Theorem 3.1, $\text{Cay}(\text{PSL}_2(p); \{A, B\})$ is an expander and hence by Proposition 2.1(iii), $v$ is $\text{PSL}_2(p)$-almost invariant. As it is also $C$-almost invariant, it is almost invariant under the set $\text{PSL}_2(p) \cdot C \cdot \text{PSL}_2(p)$ and similarly for $\text{PSL}_2(p) \cdot C' \cdot \text{PSL}_2(p)$. The union of these last two sets contains $S$. So, $v$ is $S$-almost invariant. But $\lambda(\text{Cay}(\text{PSL}_2(p^e); S)) \leq 2\sqrt{\ell}/(p + 1) < 19/20$ for every $p$ and $e$, so by Proposition 2.1(ii), $v$ is $\text{PSL}_2(p^e)$-almost invariant and by Proposition 2.1(i), the graphs $\text{Cay}(\text{PSL}_2(p^e); \{A, B, C, C'\})$ are uniform expanders. This finishes the proof of Theorem 3.7 (and hence also of Theorem 1.3). $\square$

Recall that by Proposition 2.3, Theorem 3.7 also says that the family $\{\text{SL}_2(\ell) \mid \ell \text{ a prime power}\}$ is a family of expanders. Let us now quote:

**Theorem 3.8** (Hadam [H1, Theorem 1.2]). Let $R$ be a finitely generated ring with stable range $r$ and assume that the group $\text{EL}_d(R)$ for some $d \geq r$ has Kazhdan constant $(k_0, \epsilon_0)$. Then there exist $\epsilon = \epsilon(\epsilon_0) > 0$ and $k = k(k_0) \in \mathbb{N}$ such that for every $n \geq d$, $\text{EL}_n(R)$ has Kazhdan constant $(k, \epsilon)$.

We refer the reader to [H1] for the proof. We only mention here that if $R$ is a field then its stable range is 1, and $\text{EL}_n(R)$, the group of $n \times n$ matrices over $R$ generated by the elementary matrices, is $\text{SL}_n(R)$. Also recall that a finite group $G$ has Kazhdan constant $(k, \epsilon)$ if it has a set of generators $S$ of size at most $k$ such that for every non-trivial irreducible representation $(V, \rho)$ of $G$ and for every $0 \neq v \in V$, there exists $s \in S$ such that $\|\rho(s)v - v\| \geq \epsilon \|v\|$. As is well known, this implies that $\text{Cay}(G; S)$ is an $\epsilon'$-expander for some $\epsilon'$ which depends only on $\epsilon$. All these remarks combined with Theorems 3.7 and 3.8 give:
Theorem 3.9. The groups \{SL_n(q) \mid 2 \leq n \in \mathbb{N}, q a prime power\} form a family of uniform expanders.

Remark 3.10. In the proof of Theorem 3.9, we used for \( d \geq 3 \), Theorem 3.8 of Hadad whose proof was heavily influenced by Kassabov’s proof [K1] that all \( SL_n(q), n \geq 3 \), are expanders. So our proof cannot be considered as a really different proof for \( n \geq 3 \). In [KLN], a second very different proof for \( SL_n, n \geq 3 \), was announced, based on the theory of Ramanujan complexes. But it turns out that the proof sketched there has a mistake, for which the author of the current paper takes full responsibility. The idea there was to handle \( SL_d, d \) even, say \( d = 2m \), by using the following argument: Corollary 3.4 above gives a spectral gap with respect to an unbounded subset \( S \) of \( (PGL_d(q) \) which consists of conjugates of a single element by a non-split torus \( T \). This \( T \) as a subgroup of \( G = GL_d(q) \) is inside a copy of \( H = GL_2(q^m) \). Passing from \( G \) to \( PGL_d(q) \), \( T \) is then in the image \( \bar{H} \) of \( H \). We argued there that by dividing by the center, \( T \subset \bar{H} \) and \( \bar{H} \) is isomorphic to \( PGL_2(q^m) \). (We then wanted to use Theorem 1.3 for \( \bar{H} \) to deduce that \( \bar{H} \) is an expander and to continue to argue as in the proof of Theorem 3.7.) It is not true, however, that \( \bar{H} \) is \( PGL_2(q^m) \): we divided by the center of \( G \) which is of order at most \( d \) and not by the center of \( H \) which is of order \( q^m - 1 \gg d \). So \( \bar{H} \) has a large abelian quotient and it is far from being an expander.

4. Bounded generation by \( SL_2 \)

A finite group \( G \) is said to be a product of \( s \) copies of \( SL_2 \) if there exist prime powers \( q_i \) and homomorphisms \( \varphi_i : SL_2(q_i) \rightarrow G, i = 1, \ldots, s \), such that for every \( g \in G \) there exist \( x_i \in SL_2(q_i), i = 1, \ldots, s \), with \( g = \varphi_1(x_1) \cdot \ldots \cdot \varphi_s(x_s) \).

Theorem 3.7 shows that all the groups \( SL_2(q) \) are uniform expanders (with four generators for each). It now follows from Corollary 2.2 that for a fixed \( s \), all the groups which are products of \( s \) copies of \( SL_2 \) are uniform expanders with \( 4s \) generators. We will now show that this is indeed the case for all finite simple groups of Lie type of bounded rank, excluding the groups of Suzuki type.

Theorem 4.1. There exists a function \( f : \mathbb{N} \rightarrow \mathbb{N} \) such that if \( G \) is a finite simple group of Lie type of rank \( r \), but not of Suzuki type, then it is a products of \( f(r) \) copies of \( SL_2 \).

Before giving the proof we remark that Theorem 4.1 combined with Theorem 3.9 and the result of Nikolov [N] implies Theorem 1.1. Indeed, by [N], a classical group of Lie type is a bounded products of groups of type \( SL_n(q) \) (\( n \) and \( q \) varies) and so by Theorem 3.9 they are uniform expanders. The other finite simple groups of Lie type have bounded rank and so are bounded product of \( SL_2 \) by Theorem 4.1, and hence also uniform expanders. This excludes, of course, the Suzuki groups to which every homomorphism from \( SL_2(q) \) has trivial image, since their order is not divisible by 3. Thus the validity of Theorem 1.2 for the Suzuki groups is left open.\(^1\)

\(^1\) Added in proof: as mentioned at the end of the introduction, this is not open any more.
Back to Theorem 4.1: this result has been announced in [KLN] and a model-theoretic proof based on the work of Hrushovski and Pillay [HP] was sketched there. Recently, Liebeck, Nikolov and Shalev [LNS] proved the theorem by standard group-theoretic arguments. This is somewhat more technical and requires some case by case analysis but has the advantage of yielding an explicit function $f(r)$ which is valid for every group $G$ of rank $r$. This is of importance for our application to expanders as it enables one to deduce explicit $k$ and $\varepsilon$ in Theorem 1.1.

Anyway, we will bring here the model-theoretic proof. For a nice introduction to the model theory of finite simple groups, see [W]. As there are only finitely many group types of bounded rank, we can take $G$ to be a fixed (twisted or untwisted) Chevalley group and we need to prove the result for the groups $G(F)$ when $F$ is a finite field. We will show below that each such $G(F)$ contains a copy of $(P)SL_2(F)$ as a uniformly definable subgroup. By a definable subgroup, we mean a subgroup that can be defined using a first order sentence in the language of rings with a distinguished endomorphism—the language in which $G$ is defined. By uniformly definable we mean that the subgroup $(P)SL_2(F)$ is defined by a single sentence—independent of $F$.

Assuming this fact, we can argue as follows: Let $F_i$ be an infinite family of finite fields and $K = \prod F_i/U$ an ultraproduct of them, i.e., $U$ is a non-principal ultrafilter. Thus $K$ is a pseudo-algebraically closed field (PAC, for short—see [FJ] and [HP]). Let $\tilde{G} = \prod G(F_i)/U$ be the corresponding ultraproduct of the groups $G(F_i)$. By a basic result (Point [P, Propositions 1 and 2 and Corollary 1]), $\tilde{G}$ is a simple group isomorphic to $G(K)$ and similarly the ultraproduct of the $(P)SL_2(F_i)$’s gives a subgroup $(P)SL_2(K)$ of $\tilde{G} = G(K)$.

Now, as $\tilde{G} = G(K)$ is simple, it is generated by the conjugates of $(P)SL_2(K)$. By [HP, Proposition 2.1], $G(K)$ is a product of $m < \infty$ conjugates of $(P)SL_2(K)$. This is an elementary statement about $G(K)$ and hence it is also true for $G(F_i)$ for almost all $i$. This proves what we need modulo the promised fact.

**Remark 4.2.** The model-theoretic proof gives (when one follows the arguments in [HP]) that $m \leq 4 \dim G$. Moreover, in principle one can give an explicit bound $M$ such that the above claim is true for every $F$ with $|F| > M$. The proof in [LNS] gives explicit bounds on $m$ which are usually (but not always) slightly better and are valid for all $F$.

We are left with proving our claim that $G(F)$ contains a copy of $(P)SL_2(F)$ as a uniformly definable subgroup.

If $G$ splits (i.e. untwisted type), e.g. $G = E_6$, it contains $SL_2$ as a subgroup generated by a root subgroup and its opposite. Note that a root subgroup is definable and as $SL_2$ is a bounded product of the root subgroup and its opposite, it is also definable. Of course, in this case it is even an algebraic subgroup, and a copy of $(P)SL_2(F)$ in $G(F)$ can be defined by polynomials independent of $F$.

If $G$ is twisted, but not a group of Ree type (i.e. all the simple roots of $G$ are of the same length, so the type is $A_n$, $D_8$ or $E_6$), e.g., look at $G(q) = E_6(q)$. Then $G$ is the group of points of $E_6(q^2)$ of the form $\{g \in E_6(q^2) \mid g^{F_\tau} = g^\tau\}$ where $\tau$ is the graph automorphism of $E_6$ and $F_\tau$ the Frobenius automorphism. By restriction of scalars, this is an algebraic group defined over $\mathbb{F}_q$. If the automorphism $\tau$ has a fixed
vertex, e.g. for our example $2E_6$, then $2E_6(q)$ contains a copy of $\text{SL}_2(q) \subseteq \text{E}_6(q^2)$ corresponding to this vertex, and as an $\mathbb{F}_q$-group, this is an algebraic subgroup. The argument we illustrated here with $2E_6(q)$ works equally well with the other twisted groups with fixed vertex (of course, for $2D_4$ we should take $D_4(q^3)$—but the rest is the same). By the well known classification of the simple algebraic groups over finite fields, we have covered all cases except for the twisted forms of $A_n$, $n$ even. But $2A_n$ is anyway $\text{SU}(n+1)$ which contains $\text{SU}(2)$ (as a uniformly definable algebraic subgroup) and it is well known that $\text{SU}(2,q^2)$ is isomorphic to $\text{SL}_2(q)$.

We are left with the twisted groups of Ree type: $2F_4(2^{2n+1})$ and $2G_2(3^{2n+1})$ (the other type $2B_2(2^{2n+1})$ give the Suzuki groups and these were excluded from the theorem). Now, $2F_4(2^{2n+1})$ is known (cf. [GLS, Table 2.4 VI, Table 2.4 VII, Theorems 2.4.5 and 2.48]) to have a subgroup generated by a root subgroup and its opposite which is isomorphic to $\text{SL}_2(2^{2n+1})$. (This is not the case for all roots; for some we get the Suzuki groups, but we need only one root which gives $\text{SL}_2$.) For $2G_2(3^{2n+1})$ one can argue in purely group-theoretical terms: it is known (cf. [E]) to have a unique conjugacy class of involutions and if $\tau$ is such an involution, then $C_G(\tau)$—the centralizer of $\tau$—is isomorphic to $H = \langle \tau \rangle \times \text{PSL}_2(3^{2n+1})$. Within $H$, $\text{PSL}_2(3^{2n+1})$ is the set of all commutators of $H$ (since every element of $\text{PSL}_2(q)$ is a commutator). Thus $\text{PSL}_2(3^{2n+1})$ is a uniformly definable subgroup of $2G_2(3^{2n+1})$. The proof of Theorem 4.1 (and hence of 1.1) is now complete.

Acknowledgments. The author is indebted to E. Hrushovski, Y. Shalom and U. Vishne for their useful advice, and to the NSF, ERC and BSF (US-Israel) for their support.
