# The Kodaira dimension of the moduli space of Prym varieties 

Received May 13, 2008 and in revised form September 15, 2008

#### Abstract

We study the enumerative geometry of the moduli space $\mathcal{R}_{g}$ of Prym varieties of dimension $g-1$. Our main result is that the compactication of $\mathcal{R}_{g}$ is of general type as soon as $g>13$ and $g$ is different from 15. We achieve this by computing the class of two types of cycles on $\mathcal{R}_{g}$ : one defined in terms of Koszul cohomology of Prym curves, the other defined in terms of Raynaud theta divisors associated to certain vector bundles on curves. We formulate a Prym-Green conjecture on syzygies of Prym-canonical curves. We also perform a detailed study of the singularities of the Prym moduli space, and show that for $g \geq 4$, pluricanonical forms extend to any desingularization of the moduli space.

Prym varieties provide a correspondence between the moduli spaces of curves and abelian varieties $\mathcal{M}_{g}$ and $\mathcal{A}_{g-1}$, via the Prym map $\mathcal{P}_{g}: \mathcal{R}_{g} \rightarrow \mathcal{A}_{g-1}$ from the moduli space $\mathcal{R}_{g}$ parameterizing pairs $\left[C, \eta\right.$ ], where $[C] \in \mathcal{M}_{g}$ is a smooth curve and $\eta \in$ $\operatorname{Pic}^{0}(C)[2]$ is a torsion point of order 2 . When $g \leq 6$ the Prym map is dominant and $\mathcal{R}_{g}$ can be used directly to determine the birational type of $\mathcal{A}_{g-1}$. It is known that $\mathcal{R}_{g}$ is rational for $g=2,3,4$ (see [Dol] and references therein and [Ca] for the case of genus 4) and unirational for $g=5$ (cf. [IGS] and [V2]). The situation in genus 6 is strikingly beautiful because $\mathcal{P}_{6}: \mathcal{R}_{6} \rightarrow \mathcal{A}_{5}$ is equidimensional (precisely $\operatorname{dim}\left(\mathcal{R}_{6}\right)=$ $\operatorname{dim}\left(\mathcal{A}_{5}\right)=15$ ). Donagi and Smith showed that $\mathcal{P}_{6}$ is generically finite of degree 27 (cf. [DS|) and the monodromy group equals the Weyl group $W E_{6}$ describing the incidence correspondence of the 27 lines on a cubic surface (cf. [D1]). There are three different proofs that $\mathcal{R}_{6}$ is unirational (cf. [D1], [MM], [V1]). Verra has very recently announced a proof of the unirationality of $\mathcal{R}_{7}$ (see also Theorem 0.8 for a weaker result). The Prym map $\mathcal{P}_{g}$ is generically injective for $g \geq 7$ (cf. [|FS]), although never injective. In this range, we may regard $\mathcal{R}_{g}$ as a partial desingularization of the moduli space $\mathcal{P}_{g}\left(\mathcal{R}_{g}\right) \subset \mathcal{A}_{g-1}$ of Prym varieties of dimension $g-1$.

The scheme $\mathcal{R}_{g}$ admits a suitable modular compactification $\overline{\mathcal{R}}_{g}$, which is isomorphic to (1) the coarse moduli space of the stack $\overline{\mathbf{R}}_{g}=\overline{\mathbf{M}}_{g}\left(\mathcal{B} \mathbb{Z}_{2}\right)$ of Beauville admissible double covers (cf. [B], $\overline{\mathrm{ACV}]) \text { and (2) the coarse moduli space of the stack of Prym curves }}$ (cf. [BCF]). The forgetful map $\pi: \mathcal{R}_{g} \rightarrow \mathcal{M}_{g}$ extends to a finite map $\pi: \overline{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{M}}_{g}$.

The aim of this paper is to initiate a study of the enumerative and global geometry of $\overline{\mathcal{R}}_{g}$, in particular to determine its Kodaira dimension. The main result of the paper is the following:
Theorem 0.1. The moduli space of Prym varieties $\overline{\mathcal{R}}_{g}$ is of general type for $g>13$ and $g \neq 15$. The Kodaira dimension of $\overline{\mathcal{R}}_{15}$ is at least 1 .
We point out in Remark 2.9 that the existence of an effective divisor $D \in \operatorname{Eff}\left(\overline{\mathcal{M}}_{15}\right)$ of slope $s(D)<6+12 /(g+1)=27 / 4$ (that is, violating the Harris-Morrison Slope Conjecture on $\overline{\mathcal{M}}_{15}$ ), would imply that $\overline{\mathcal{R}}_{15}$ is of general type. There are known examples of divisors $D \in \operatorname{Eff}\left(\overline{\mathcal{M}}_{g}\right)$ satisfying $s(D)<6+12 /(g+1)$ for every genus of the form $g=s(2 s+s i+i+1)$ with $s \geq 2$ and $i \geq 0$ (cf. [F1], [F2]). No such examples have been found yet on $\overline{\mathcal{M}}_{15}$, though they are certainly expected to exist.

The normal variety $\overline{\mathcal{R}}_{g}$ has finite quotient singularities and an important part of the proof is concerned with showing that pluricanonical forms defined on the smooth part $\overline{\mathcal{R}}_{g}^{\text {reg }} \subset \overline{\mathcal{R}}_{g}$ can be lifted to any resolution of singularities $\widehat{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{R}}_{g}$, that is, we have isomorphisms

$$
H^{0}\left(\overline{\mathcal{R}}_{g}^{\mathrm{reg}}, K_{\overline{\mathcal{R}}_{g}}^{\otimes l}\right) \cong H^{0}\left(\widehat{\mathcal{R}}_{g}, K_{\widehat{\mathcal{R}}_{g}}^{\otimes l}\right)
$$

for $l \geq 0$. This is achieved in the last section of the paper. The locus of non-canonical singularities in $\overline{\mathcal{R}}_{g}$ is also explicitly described: A Prym curve $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$ is a noncanonical singularity if and only if $X$ has an elliptic tail $C$ with $\operatorname{Aut}(C)=\mathbb{Z}_{6}$ such that the line bundle $\eta_{C} \in \operatorname{Pic}^{0}(C)[2]$ is trivial (cf. Theorem 6.7.

We outline the strategy to prove that $\overline{\mathcal{R}}_{g}$ is of general type for given $g$. If $\lambda=$ $\pi^{*}(\lambda) \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right)$ is the pull-back of the Hodge class and $\delta_{0}^{\prime}, \delta_{0}^{\prime \prime}, \delta_{0}^{\mathrm{ram}} \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right)$ and $\delta_{i}, \delta_{g-i}, \delta_{i: g-i} \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right)$ for $1 \leq i \leq[g / 2]$ are boundary divisor classes such that

$$
\pi^{*}\left(\delta_{0}\right)=\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}+2 \delta_{0}^{\mathrm{ram}} \quad \text { and } \quad \pi^{*}\left(\delta_{i}\right)=\delta_{i}+\delta_{g-i}+\delta_{i: g-i} \quad \text { for } 1 \leq i \leq[g / 2]
$$

(see Section 2 for a precise definition of these classes), then one has the formula

$$
K_{\overline{\mathcal{R}}_{g}} \equiv 13 \lambda-2\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-3 \delta_{0}^{\mathrm{ram}}-2 \sum_{i=1}^{[g / 2]}\left(\delta_{i}+\delta_{g-i}+\delta_{i: g-i}\right)-\left(\delta_{1}+\delta_{g-1}+\delta_{1: g-1}\right)
$$

We show that this class is big by explicitly constructing effective divisors $D$ on $\overline{\mathcal{R}}_{g}$ such that one can write $K_{\overline{\mathcal{R}}_{g}} \equiv \alpha \cdot \lambda+\beta \cdot D+\{$ effective combination of boundary classes\} for certain $\alpha, \beta \in \mathbb{Q}_{>0}$ (see (2) for the inequalities the coefficients of such $D$ must satisfy).

We carry out an enumerative study of divisors on $\overline{\mathcal{R}}_{g}$ defined in terms of pairs [ $C, \eta$ ] such that the 2 -torsion point $\eta \in \operatorname{Pic}^{0}(C)$ is transversal with respect to the theta divisors associated to certain stable vector bundles on $C$. We fix integers $k \geq 2$ and $b \geq 0$ and then define the integers

$$
i:=k b+k-b-2, \quad r:=k b+k-2, \quad g:=i k+1, \quad d:=r k .
$$

The Brill-Noether number $\rho(g, r, d):=g-(r+1)(g-d+r)=0$ and a general [C] $\in \mathcal{M}_{g}$ carries a finite number of line bundles $L \in W_{d}^{r}(C)$. For each such line
bundle $L$, if $Q_{L}$ denotes the dual of the Lazarsfeld bundle defined by the exact sequence (see [L])

$$
0 \rightarrow Q_{L}^{\vee} \rightarrow H^{0}(C, L) \otimes \mathcal{O}_{C} \rightarrow L \rightarrow 0
$$

we compute that $\mu\left(Q_{L}\right)=d / r=k$ and then $\mu\left(\bigwedge^{i} Q_{L}\right)=i k=g-1$. In these circumstances we define the Raynaud divisor (degeneration locus of virtual codimension 1)

$$
\Theta_{\wedge^{i} Q_{L}}:=\left\{\eta \in \operatorname{Pic}^{0}(C): H^{0}\left(C, \bigwedge^{i} Q_{L} \otimes \eta\right) \neq 0\right\}
$$

This is a virtual divisor inside $\operatorname{Pic}^{0}(C)$, in the sense that either $\Theta_{\wedge^{i} Q_{L}}=\operatorname{Pic}^{0}(C)$ or else $\Theta_{\wedge^{i} Q_{L}}$ is a divisor on $\operatorname{Pic}^{0}(C)$ belonging to the linear system $\left|\binom{r}{i} \theta\right|$ (cf. [R]). We study the relative position of $\eta$ with respect to $\Theta^{\wedge}{ }^{i} Q_{L}$ and introduce the following locus on $\overline{\mathcal{R}}_{g}$ :

$$
\mathcal{D}_{g: k}:=\left\{[C, \eta] \in \mathcal{R}_{g}: \exists L \in W_{d}^{r}(C) \text { such that } \eta \in \Theta_{\wedge^{i} Q_{L}}\right\} .
$$

When $k=2, i=b$, then $g=2 i+1, d=2 g-2$ and $\mathcal{D}_{2 i+1: 2}$ has a new incarnation using the proof of the Minimal Resolution Conjecture [FMP]. In this case, $L=K_{C}$ (a genus $g$ curve has only one $\mathfrak{g}_{2 g-2}^{g-1}!$ ) and [FMP] gives an identification of cycles

$$
\Theta_{\bigwedge^{i} Q_{K_{C}}}=C_{i}-C_{i} \subset \operatorname{Pic}^{0}(C)
$$

where the right-hand side stands for the $i$-th difference variety of $C$.
We prove in Section 2 that $\mathcal{D}_{g: k}$ is an effective divisor on $\mathcal{R}_{g}$. By specialization to the $k$-gonal locus $\mathcal{M}_{g, k}^{1} \subset \mathcal{M}_{g}$, we show that for a generic $[C, \eta] \in \mathcal{R}_{g}$ the vanishing $H^{0}\left(C, \bigwedge^{i} Q_{L} \otimes \eta\right)=0$ holds for every $L \in W_{d}^{r}(C)$ (Theorem 2.3. Then we extend the determinantal structure of $\mathcal{D}_{g: k}$ to a partial compactification of $\mathcal{R}_{g}$, which enables us to compute the class of the compactification $\overline{\mathcal{D}}_{g: k}$. Precisely we construct two vector bundles $\mathcal{E}$ and $\mathcal{F}$ over a stack $\overline{\mathbf{R}}_{g}^{0}$ which is a partial compactification of $\mathbf{R}_{g}$, such that $\operatorname{rank}(\mathcal{E})=\operatorname{rank}(\mathcal{F})$, together with a vector bundle homomorphism $\phi: \mathcal{E} \rightarrow \mathcal{F}$ such that $Z_{1}(\phi) \cap \mathcal{R}_{g}=\mathcal{D}_{g}$ :k. Then we explicitly determine the class $c_{1}(\mathcal{F}-\mathcal{E}) \in A^{1}\left(\overline{\mathbf{R}}_{g}^{0}\right)$ (Theorem 2.8). The cases of interest for determining the Kodaira dimension of $\overline{\mathcal{R}}_{g}$ are when $k=2,3$, for which we obtain the following results:

Theorem 0.2. The closure of the divisor $\mathcal{D}_{2 i+1: 2}=\left\{[C, \eta] \in \mathcal{R}_{2 i+1}: h^{0}\left(C, \bigwedge^{i} Q_{K_{C}} \otimes\right.\right.$ $\eta) \geq 1\}$ inside $\overline{\mathcal{R}}_{2 i+1}$ has class given by the following formula in $\operatorname{Pic}\left(\overline{\mathcal{R}}_{2 i+1}\right)$ :
$\overline{\mathcal{D}}_{2 i+1: 2}$
$\equiv \frac{1}{2 i-1}\binom{2 i}{i}\left((3 i+1) \lambda-\frac{i}{2}\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-\frac{2 i+1}{4} \delta_{0}^{\mathrm{ram}}-(3 i-1) \delta_{g-1}-i\left(\delta_{1: g-1}+\delta_{1}\right)-\cdots\right)$.
To illustrate Theorem 0.2 in the simplest case, $i=1$ hence $g=3$, we write $\mathcal{D}_{3: 2}=$ $\left\{[C, \eta] \in \mathcal{R}_{3}: \eta=\mathcal{O}_{C}(x-y), x, y \in C\right\}$. The analysis carried out in Section 5 shows that the vector bundle morphism $\phi: \mathcal{E} \rightarrow \mathcal{F}$ is generically non-degenerate along the
boundary divisors $\Delta_{0}^{\prime}, \Delta_{0}^{\mathrm{ram}} \subset \overline{\mathcal{R}}_{3}$ and degenerate (with multiplicity 1) along the divisor $\Delta_{0}^{\prime \prime} \subset \overline{\mathcal{R}}_{3}$ of Wirtinger covers. Theorem 0.2 reads

$$
\overline{\mathcal{D}}_{3: 2} \equiv c_{1}(\mathcal{F}-\mathcal{E})-\delta_{0}^{\prime \prime} \equiv 8 \lambda-\delta_{0}^{\prime}-2 \delta_{0}^{\prime \prime}-\frac{3}{2} \delta_{0}^{\mathrm{ram}}-6 \delta_{1}-4 \delta_{2}-2 \delta_{1: 2} \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{3}\right)
$$

and then $\pi_{*}\left(\overline{\mathcal{D}}_{3: 2}\right)=56\left(9 \lambda-\delta_{0}-3 \delta_{1}\right)=56 \cdot \overline{\mathcal{M}}_{3,2}^{1} \in \operatorname{Pic}\left(\overline{\mathcal{M}}_{3}\right)$ (see Theorem 5.1). Theorem 0.2 is consistent with the following elementary fact (see e.g. [HF]): If $[\tilde{C} \rightarrow C] \in \mathcal{R}_{3}$ is an étale double cover, then $[\widetilde{C}] \in \mathcal{M}_{5}$ is hyperelliptic if and only if $[C] \in \mathcal{M}_{3}$ is hyperelliptic and $\eta=\mathcal{O}_{C}(x-y)$, with $x, y \in C$ being Weierstrass points.
Theorem 0.3. For $b \geq 1$ and $r=3 b+1$ the class of the divisor $\overline{\mathcal{D}}_{6 b+4: 3}$ on $\overline{\mathcal{R}}_{6 b+4}$ is given by

$$
\begin{aligned}
\overline{\mathcal{D}}_{g: 3} & \equiv \frac{4}{r}\binom{6 b+3}{b, 2 b, 3 b+3} \\
& \times\left((3 b+2)(b+2) \lambda-\frac{3 b^{2}+7 b+3}{6}\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-\frac{24 b^{2}+47 b+21}{24} \delta_{0}^{\mathrm{ram}}-\cdots\right) .
\end{aligned}
$$

Theorems 2.80 .2 and 0.3 specify precisely the $\lambda, \delta_{0}^{\prime}, \delta_{0}^{\prime \prime}$ and $\delta_{0}^{\text {ram }}$ coefficients in the expansion of $\left[\overline{\mathcal{D}}_{g: k}\right]$. Good lower bounds for the remaining boundary coefficients of $\left[\overline{\mathcal{D}}_{g: k}\right]$ can be obtained using Proposition 1.9 The information contained in Theorems 0.2 and 0.3 is sufficient to finish the proof of Theorem 0.1 for odd genus $g=2 i+1 \geq 15$.

When $b=0$, hence $i=r=k-2$, Theorem 2.8 has the following interpretation:
Theorem 0.4. Fix integers $k \geq 3, r=k-2$ and $g=(k-1)^{2}$. The locus

$$
\mathcal{D}_{g: k}:=\left\{[C, \eta] \in \mathcal{R}_{g}: \exists L \in W_{k(k-2)}^{k-2}(C) \text { such that } H^{0}(C, L \otimes \eta) \neq 0\right\}
$$

is a divisor on $\mathcal{R}_{g}$. The class of its compactification inside $\overline{\mathcal{R}}_{g}$ is given by the formula

$$
\begin{aligned}
& \overline{\mathcal{D}}_{g: k} \equiv g!\frac{1!2!\cdots(k-2)!}{(k-1)!\cdots(2 k-3)!\left(k^{2}-2 k-1\right)}\left(\left(k^{4}-4 k^{3}+11 k^{2}-14 k+2\right) \lambda\right. \\
&\left.-\frac{k(k-2)\left(k^{2}-2 k+5\right)}{12}\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-\frac{\left(k^{2}-2 k+3\right)\left(2 k^{2}-4 k+1\right)}{12} \delta_{0}^{\mathrm{ram}}-\cdots\right) \\
& \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right) .
\end{aligned}
$$

When $k=3$ and $g=4$, the divisor $\mathcal{D}_{4: 3}$ consists of Prym curves $[C, \eta] \in \mathcal{R}_{4}$ for which the plane Prym-canonical model $\iota: C \xrightarrow{\left|K_{C} \otimes \eta\right|} \mathbf{P}^{2}$ has a triple point. Note that for a general $[C, \eta] \in \mathcal{R}_{4}, l(C)$ is a 6-nodal sextic. We can then verify the formula

$$
\pi_{*}\left(\overline{\mathcal{D}}_{4: 3}\right)=60\left(34 \lambda-4 \delta_{0}-14 \delta_{1}-18 \delta_{2}\right)=60 \cdot \overline{\mathcal{G P}}_{4,3}^{1} \in \operatorname{Pic}\left(\overline{\mathcal{M}}_{4}\right)
$$

where $\overline{\mathcal{G P}}_{4,3}^{1} \subset \overline{\mathcal{M}}_{4}$ is the divisor of curves with a vanishing theta-null. This is consistent with the set-theoretic equality $\pi\left(\mathcal{D}_{4: 3}\right)=\mathcal{G} \mathcal{P}_{4,3}^{1}$, which can be easily established (see Theorem 5.4.

Another case which has a simple interpretation is when $b=1, i=r-1$, and then $g=(2 k-1)(k-1), d=2 k(k-1)$. Since $\operatorname{rank}\left(Q_{L}\right)=r$ and $\operatorname{det}\left(Q_{L}\right)=L$, by duality we have $\bigwedge^{i} Q_{L}=M_{L} \otimes L$, hence points $[C, \eta] \in \mathcal{D}_{(2 k-1)(k-1): k}$ can be described purely in terms of multiplication maps of sections of line bundles on $C$ :

Theorem 0.5. Fix integers $k \geq 2$ and $g=(2 k-1)(k-1)$. The locus

$$
\begin{aligned}
\mathcal{D}_{g: k}=\left\{[C, \eta] \in \mathcal{R}_{g}:\right. & \exists L \in W_{2 k(k-1)}^{2 k-2}(C) \\
& \text { with } \left.H^{0}(L) \otimes H^{0}(L \otimes \eta) \rightarrow H^{0}\left(L^{\otimes 2} \otimes \eta\right) \text { not bijective }\right\}
\end{aligned}
$$

is a divisor on $\mathcal{R}_{g}$. The class of its compactification inside $\overline{\mathcal{R}}_{g}$ equals

$$
\begin{aligned}
& \overline{\mathcal{D}}_{g: k} \equiv g!\frac{1!2!\cdots(k-1)!}{3\left(2 k^{2}-3 k-1\right)(2 k-1)!(2 k)!\cdots(3 k-2)!} \\
& \times\left(6\left(8 k^{5}-36 k^{4}+78 k^{3}-95 k^{2}+49 k-6\right) \lambda-\left(8 k^{5}-36 k^{4}+70 k^{3}-71 k^{2}+29 k-2\right)\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)\right. \\
& \\
& \left.\quad-\frac{1}{2}\left(32 k^{5}-144 k^{4}+262 k^{3}-245 k^{2}+107 k-14\right) \delta_{0}^{\mathrm{ram}}-\cdots\right) .
\end{aligned}
$$

The second class of (virtual) divisors is provided by Koszul divisors on $\overline{\mathcal{R}}_{g}$. For a pair ( $C, L$ ) consisting of a curve $[C] \in \mathcal{M}_{g}$ and a line bundle $L \in \operatorname{Pic}(C)$, we denote by $K_{i, j}(C, L)$ its $(i, j)$-th Koszul cohomology group (cf. [L] $]$. For a point $[C, \eta] \in \mathcal{R}_{g}$ we set $L:=K_{C} \otimes \eta$ and we stratify $\mathcal{R}_{g}$ using the syzygies of the Prym-canonical curve $C \xrightarrow{|L|} \mathbf{P}^{g-2}$. We define the stratum

$$
\mathcal{U}_{g, i}:=\left\{[C, \eta] \in \mathcal{R}_{g}: K_{i, 2}\left(C, K_{C} \otimes \eta\right) \neq \emptyset\right\}
$$

that is, $\mathcal{U}_{g, i}$ consists of those Prym curves $[C, \eta] \in \mathcal{R}_{g}$ for which the Prym-canonical model $C \xrightarrow{|L|} \mathbf{P}^{g-2}$ fails to satisfy the Green-Lazarsfeld property $\left(N_{i}\right)$ in the sense of [GL], [L].

Theorem 0.6. There exist two vector bundles $\mathcal{G}_{i, 2}$ and $\mathcal{H}_{i, 2}$ of the same rank defined over a partial compactification $\widetilde{\mathbf{R}}_{2 i+6}$ of the stack $\mathbf{R}_{2 i+6}$, together with a morphism $\phi$ : $\mathcal{H}_{i, 2} \rightarrow \mathcal{G}_{i, 2}$ such that

$$
\mathcal{U}_{2 i+6, i}:=\left\{[C, \eta] \in \widetilde{\mathcal{R}}_{2 i+6}: K_{i, 2}\left(C, K_{C} \otimes \eta\right) \neq 0\right\}
$$

is the degeneracy locus of the map $\phi$. The virtual class of $\left[\overline{\mathcal{U}}_{2 i+6, i}\right]$ is given by the formula

$$
\left[\overline{\mathcal{U}}_{2 i+6, i}\right]^{\mathrm{virt}}=c_{1}\left(\mathcal{G}_{i, 2}-\mathcal{H}_{i, 2}\right)=\binom{2 i+2}{i}\left(\frac{3(2 i+7)}{i+3} \lambda-\frac{3}{2} \delta_{0}^{\mathrm{ram}}-\left(\delta_{0}^{\prime}+\alpha \delta_{0}^{\prime \prime}\right)-\cdots\right),
$$

where the constant $\alpha$ satisfies $\alpha \geq 1$.

The compactification $\widetilde{\mathbf{R}}_{g}$ has the property that if $\widetilde{\mathcal{R}}_{g} \subset \overline{\mathcal{R}}_{g}$ denotes its coarse moduli space, then $\operatorname{codim}\left(\pi^{-1}\left(\mathcal{M}_{g} \cup \Delta_{0}\right)-\widetilde{\mathcal{R}}_{g}\right) \geq 2$. In particular Theorem 0.6 precisely determines the coefficients of $\lambda, \delta_{0}^{\prime}, \delta_{0}^{\prime \prime}$ and $\delta_{0}^{\text {ram }}$ in the expansion of $\left[\overline{\mathcal{U}}_{2 i+6, i}\right]^{\text {virt }}$. We also show that if $g<2 i+6$ then $K_{i, 2}\left(C, K_{C} \otimes \eta\right) \neq \emptyset$ for any $[C, \eta] \in \mathcal{R}_{g}$. By analogy with the case of canonical curves and the classical M . Green Conjecture on syzygies of canonical curves (see [V0]), we conjecture that the morphism of vector bundles $\phi: \mathcal{G}_{i, 2} \rightarrow \mathcal{H}_{i, 2}$ over $\widetilde{\mathbf{R}}_{2 i+6}$ is generically non-degenerate:

Conjecture 0.7 (Prym-Green Conjecture). For a generic point $[C, \eta] \in \mathcal{R}_{g}$ and $g \geq$ $2 i+6$, we have $K_{i, 2}\left(C, K_{C} \otimes \eta\right)=0$. Equivalently, the Prym-canonical curve $C \xrightarrow{\left|K_{C} \otimes \eta\right|} \mathbf{P}^{g-2}$ satisfies the Green-Lazarsfeld property $\left(N_{i}\right)$ whenever $g \geq 2 i+6$. For $g=2 i+6$, the locus $\mathcal{U}_{2 i+6, i}$ is an effective divisor on $\mathcal{R}_{2 i+6}$.

Proposition 3.1 shows that, if true, Conjecture 0.7 is sharp. In [F4] we verify the Prym-Green Conjecture for $g=2 i+6$ with $0 \leq i \leq 4, i \neq 3$. In particular, this together with Theorem 0.6 proves that $\overline{\mathcal{R}}_{g}$ is of general type for $g=14$.

The strata $\mathcal{U}_{g, i}$ have been considered before for $i=0,1$, in connection with the Prym-Torelli problem. Unlike the classical Torelli problem, the Prym-Torelli problem is a subtle question: Donagi's tetragonal construction shows that $\mathcal{P}_{g}$ fails to be injective over points $[C, \eta] \in \pi^{-1}\left(\mathcal{M}_{g, 4}^{1}\right)$ where the curve $C$ is tetragonal (cf. [D2]). The locus $\mathcal{U}_{g, 0}$ consists of those points $[C, \eta] \in \mathcal{R}_{g}$ where the differential

$$
\left(d \mathcal{P}_{g}\right)_{[C, \eta]}: H^{0}\left(C, K_{C}^{\otimes 2}\right)^{\vee} \rightarrow\left(\operatorname{Sym}^{2} H^{0}\left(C, K_{C} \otimes \eta\right)\right)^{\vee}
$$

is not injective and thus the infinitesimal Prym-Torelli theorem fails. It is known that $\left(d \mathcal{P}_{g}\right)_{[C, \eta]}$ is generically injective for $g \geq 6$ (cf. [B], or [De, Corollaire 2.3]), that is, $\mathcal{U}_{g, 0}$ is a proper subvariety of $\mathcal{R}_{g}$. In particular, for $g=6$ the locus $\mathcal{U}_{6,0}$ is a divisor of $\mathcal{R}_{6}$, which gives another proof of Conjecture 0.7 for $i=0$.

Debarre proved that $\mathcal{U}_{g, 1}$ is a proper subvariety of $\mathcal{R}_{g}$ for $g \geq 9$ (cf. [De, Théorème 2.2]). This immediately implies that for $g \geq 9$ the Prym map $\mathcal{P}_{g}$ is generically injective, hence the Prym-Torelli theorem holds generically. Debarre's proof unfortunately does not cover the interesting case $g=8$, when $\mathcal{U}_{8,1} \subset \mathcal{R}_{8}$ is an effective divisor (cf. [F4]).

The proof of Theorem 0.1 is finished in Section 4, using in an essential way results from [F3]: We set $g^{\prime}:=1+\frac{g-1}{g}\binom{2 g-1}{g-1}$ and then we consider the rational map which associates to a curve one of its Brill-Noether loci

$$
\phi: \overline{\mathcal{M}}_{2 g-1} \cdots \overline{\mathcal{M}}_{1+\frac{g-1}{g}\left({ }_{g-1}^{2 g}\right)}, \quad \phi[Y]:=W_{g+1}^{1}(Y),
$$

where $W_{g+1}^{1}(Y):=\left\{L \in \operatorname{Pic}^{g+1}(Y): h^{0}(Y, L) \geq 2\right\}$. If $\chi: \overline{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{M}}_{2 g-1}$ is the map given by $\chi([C, \eta]):=[\tilde{C}]$, where $f: \tilde{C} \rightarrow C$ is the étale double cover with the property that $f_{*} \mathcal{O}_{\tilde{C}}=\mathcal{O}_{C} \oplus \eta$, then using [F3] we compute the slope of myriads of effective divisors of type $\chi^{*} \phi^{*}(A)$, where $A \in \operatorname{Ample}\left(\overline{\mathcal{M}}_{g^{\prime}}\right)$. This proves Theorem 0.1 for even genus $g=2 i+6 \geq 18$.

We mention in passing, as an immediate application of Proposition 1.9, a different proof of the statement that $\overline{\mathcal{R}}_{g}$ has good rationality properties for low $g$ (see again the introduction for the history of this problem). Our proof is quite simple and uses only numerical properties of Lefschetz pencils of curves on $K 3$ surfaces:

Theorem 0.8. For all $g \leq 7$, the Kodaira dimension of $\overline{\mathcal{R}}_{g}$ is $-\infty$.
We close by summarizing the structure of the paper. In Section 1 we introduce the stack $\overline{\mathbf{R}}_{g}$ of Prym curves and determine the Chern classes of certain tautological vector bundles. In Section 2 we carry out the enumerative study of the divisors $\overline{\mathcal{D}}_{g: k}$ while in Section 3 we study Koszul divisors on $\overline{\mathcal{R}}_{g}$ in connection with the Prym-Green Conjecture. The proof of Theorem 0.1 is completed in Section 4 while Section 5 is concerned with the enumerative geometry of $\overline{\mathcal{R}}_{g}$ for $g \leq 5$. In Section 6 we describe the behaviour of singularities of pluricanonical forms of $\overline{\mathcal{R}}_{g}$. There is a significant overlap between some of the results of this paper and those of [Be]. Among the things we use from [Be] we mention the description of the branch locus of $\pi$ and the fact that $\overline{\mathcal{R}}_{g}$ is isomorphic to the coarse moduli space of $\overline{\mathbf{M}}_{g}\left(\mathcal{B} \mathbb{Z}_{2}\right)$ (see Section 1). However, some of the results in $[\overline{\mathrm{Be}}]$ are not correct, in particular the statement in [Be, Chapter 3] on singularities of $\overline{\mathcal{R}}_{g}$. Hence we carried out a detailed study of singularities of $\overline{\mathcal{R}}_{g}$ in Section 6 of our paper.

## 1. The stack of Prym curves

In this section we review a few facts about compactifications of $\mathcal{R}_{g}$. As a matter of terminology, if $\mathbf{M}$ is a Deligne-Mumford stack, we denote by $\mathcal{M}$ its coarse moduli space (this is contrary to the convention set in $\overline{A C V}$ but it makes sense, at least from a historical point of view). All the Picard groups of stacks or schemes we are going to consider are with rational coefficients.

We recall that $\pi: \mathcal{R}_{g} \rightarrow \mathcal{M}_{g}$ is the $\left(2^{2 g}-1\right)$-sheeted cover which forgets the point of order 2 and we denote by $\overline{\mathcal{R}}_{g}$ the normalization of $\overline{\mathcal{M}}_{g}$ in the function field of $\mathcal{R}_{g}$. By definition, $\overline{\mathcal{R}}_{g}$ is a normal variety and $\pi$ extends to a finite ramified covering $\pi: \overline{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{M}}_{g}$. The local behaviour of this branched cover has been studied in the thesis of M. Bernstein [Be] as well as in the paper [BCF]. In particular, the scheme $\overline{\mathcal{R}}_{g}$ has two distinct modular incarnations which we now recall. If $X$ is a nodal curve, a smooth rational component $E \subset X$ is said to be exceptional if $\#(E \cap \overline{X-E})=2$. The curve $X$ is said to be quasi-stable if any two exceptional components of $X$ are disjoint. Thus a quasi-stable curve is obtained from a stable curve by blowing up each node at most once. We denote by $[\operatorname{st}(X)] \in \overline{\mathcal{M}}_{g}$ the stable model of $X$. We have the following definition (cf. [BCF]):

Definition 1.1. A Prym curve of genus $g$ consists of a triple $(X, \eta, \beta)$, where $X$ is a genus $g$ quasi-stable curve, $\eta \in \operatorname{Pic}^{0}(X)$ is a line bundle of degree 0 such that $\eta_{E}=\mathcal{O}_{E}(1)$ for every exceptional component $E \subset X$, and $\beta: \eta^{\otimes 2} \rightarrow \mathcal{O}_{X}$ is a sheaf homomorphism which is generically non-zero along each non-exceptional component of $X$.

A family of Prym curves over a base scheme $S$ consists of a triple $(\mathcal{X} \xrightarrow{f} S, \eta, \beta)$, where $f: \mathcal{X} \rightarrow S$ is a flat family of quasi-stable curves, $\eta \in \operatorname{Pic}(\mathcal{X})$ is a line bundle and $\beta: \eta^{\otimes 2} \rightarrow \mathcal{O}_{\mathcal{X}}$ is a sheaf homomorphism, such that for every point $s \in S$ the restriction $\left(X_{s}, \eta_{X_{s}}, \beta_{X_{s}}: \eta_{X_{s}}^{\otimes 2} \rightarrow \mathcal{O}_{X_{s}}\right)$ is a Prym curve.

We denote by $\overline{\mathbf{R}}_{g}$ the non-singular Deligne-Mumford stack of Prym curves of genus $g$. The main result of $[\overline{B C F}]$ is that the coarse moduli space of $\overline{\mathbf{R}}_{g}$ is isomorphic to the normalization of $\overline{\mathcal{M}}_{g}$ in the function field of $\mathcal{R}_{g}$. On the other hand, it is proved in [Be] that $\overline{\mathcal{R}}_{g}$ is also isomorphic to the coarse moduli space of the Deligne-Mumford stack $\overline{\mathbf{M}}_{g}\left(\mathcal{B} \mathbb{Z}_{2}\right)$ of $\mathbb{Z}_{2}$-admissible double covers introduced in [B] and later in [ACV]. For intersection theory calculations the language of Prym curves is better suited than that of admissible covers. In particular, the existence of a degree 0 line bundle $\eta$ over the universal Prym curve will be often used to compute the Chern classes of various tautological vector bundles defined over $\overline{\mathbf{R}}_{g}$. Throughout this paper we use the isomorphism between rational Picard groups $\epsilon^{*}: \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right) \rightarrow \operatorname{Pic}\left(\overline{\mathbf{R}}_{g}\right)$ induced by the map $\epsilon: \overline{\mathbf{R}}_{g} \rightarrow \overline{\mathcal{R}}_{g}$ from the stack to its coarse moduli space.

Remark 1.2. If $(X, \eta, \beta)$ is a Prym curve with exceptional components $E_{1}, \ldots, E_{r}$ and $\left\{p_{i}, q_{i}\right\}=E_{i} \cap \overline{X-E_{i}}$ for $i=1, \ldots, r$, then obviously $\beta_{E_{i}}=0$. Moreover, if $\tilde{X}:=$ $\overline{X-\bigcup_{i=1}^{r} E_{i}}$ (viewed as a subcurve of $X$ ), then we have an isomorphism of sheaves

$$
\begin{equation*}
\eta_{\tilde{X}}^{\otimes 2} \xrightarrow{\sim} \mathcal{O}_{\tilde{X}}\left(-p_{1}-q_{1}-\cdots-p_{r}-q_{r}\right) . \tag{1}
\end{equation*}
$$

It is straightforward to describe all Prym curves $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$ whose stable model has a prescribed topological type. We do this when $s t(X)$ is a 1-nodal curve and we determine in the process the boundary components of $\overline{\mathcal{R}}_{g}-\mathcal{R}_{g}$.

Example 1.3 (Curves of compact type). If $\operatorname{st}(X)=C \cup D$ is a union of two smooth curves $C$ and $D$ of genus $i$ and $g-i$ respectively meeting transversally at a point, we use (1) to note that $X=C \cup D$ (that is, $X$ has no exceptional components). The line bundle $\eta$ on $X$ is determined by the choice of two line bundles $\eta_{C} \in \operatorname{Pic}^{0}(C)$ and $\eta_{D} \in$ $\operatorname{Pic}^{0}(D)$ satisfying $\eta_{C}^{\otimes 2}=\mathcal{O}_{C}$ and $\eta_{D}^{\otimes 2}=\mathcal{O}_{D}$ respectively. This shows that for $1 \leq i \leq$ [g/2] the pull-back under $\pi$ of the boundary divisor $\Delta_{i} \subset \overline{\mathcal{M}}_{g}$ splits into three irreducible components

$$
\pi^{*}\left(\Delta_{i}\right)=\Delta_{i}+\Delta_{g-i}+\Delta_{i: g-i}
$$

where the generic point of $\Delta_{i} \subset \overline{\mathcal{R}}_{g}$ is of the form $\left[C \cup D, \eta_{C} \neq \mathcal{O}_{C}, \eta_{D}=\mathcal{O}_{D}\right]$, the generic point of $\Delta_{g-i}$ is of the form [ $C \cup D, \eta_{C}=\mathcal{O}_{C}, \eta_{D} \neq \mathcal{O}_{D}$ ]), and finally $\Delta_{i: g-i}$ is the closure of the locus of points $\left[C \cup D, \eta_{C} \neq \mathcal{O}_{C}, \eta_{D} \neq \mathcal{O}_{D}\right.$ ] (see also [Be, p. 9]).

Example 1.4 (Irreducible one-nodal curves). If $s t(X)=C_{y q}:=C /(y \sim q)$, where $[C, y, q] \in \mathcal{M}_{g-1,2}$, then there are two possibilities, depending on whether $X$ has an exceptional component or not. Suppose first that $X=C^{\prime}$ and $\eta \in \operatorname{Pic}^{0}(X)$. If $v: C \rightarrow X$ is the normalization map, then there is an exact sequence

$$
1 \rightarrow \mathbb{C}^{*} \rightarrow \operatorname{Pic}^{0}(X) \xrightarrow{\nu^{*}} \operatorname{Pic}^{0}(C) \rightarrow 0
$$

Thus $\eta$ is determined by a (non-trivial) line bundle $\eta_{C}:=v^{*}(\eta) \in \operatorname{Pic}^{0}(C)$ satisfying $\eta_{C}^{\otimes 2}=\mathcal{O}_{C}$ together with an identification of the fibres $\eta_{C}(y)$ and $\eta_{C}(q)$. If $\eta_{C}=\mathcal{O}_{C}$, then there is a unique way to identify the fibres $\eta_{C}(y)$ and $\eta_{C}(q)$ such that $\eta \neq \mathcal{O}_{X}$, and this corresponds to the classical Wirtinger cover of $X$. We denote by $\Delta_{0}^{\prime \prime}=\Delta_{0}^{\text {wir }}$ the closure in $\overline{\mathcal{R}}_{g}$ of the locus of Wirtinger covers. If $\eta_{C} \neq \mathcal{O}_{C}$, then for each such choice of $\eta_{C} \in \operatorname{Pic}^{0}(C)[2]$ there are two ways to glue $\eta_{C}(y)$ and $\eta_{C}(q)$. This provides another $2 \times\left(2^{2 g-2}-1\right)$ Prym curves having $C^{\prime}$ as their stable model. We set $\Delta_{0}^{\prime} \subset \overline{\mathcal{R}}_{g}$ to be the closure of the locus of Prym curves with $\eta_{C} \neq \mathcal{O}_{C}$.

We now treat the case when $X=C \cup_{\{y, q\}} E$, with $E$ being an exceptional component. Then $\eta_{E}=\mathcal{O}_{E}(1)$ and $\eta_{C}^{\otimes 2}=\mathcal{O}_{C}(-y-q)$. The analysis carried out in [BCF, Proposition 12] shows that $\pi$ is simply ramified at each of these $2^{2 g-2} \operatorname{Prym}$ curves in $\pi^{-1}\left(\left[C^{\prime}\right]\right)$. We denote by $\Delta_{0}^{\mathrm{ram}} \subset \overline{\mathcal{R}}_{g}$ the closure of the locus of Prym curves $\left[C \cup_{\{y, q\}} E, \eta, \beta\right.$ ] and then $\Delta_{0}^{\mathrm{ram}}$ is the ramification divisor of $\pi$. Moreover one has the relation

$$
\pi^{*}\left(\Delta_{0}\right)=\Delta_{0}^{\prime}+\Delta_{0}^{\prime \prime}+2 \Delta_{0}^{\mathrm{ram}}
$$

It is easy to establish a dictionary between Prym curves and Beauville admissible covers. We explain how to do this in codimension 1 in $\overline{\mathcal{R}}_{g}$ (see also [D2, Example 1.9]). The general point of $\Delta_{0}^{\prime}$ corresponds to an étale double cover $[\tilde{C} \xrightarrow{f} C] \in \mathcal{R}_{g-1}$ induced by $\eta_{C}$. We denote by $y_{i}, q_{i}(i=1,2)$ the points lying in $f^{-1}(y)$ and $f^{-1}(q)$ respectively. Then

$$
\overline{\mathcal{M}}_{2 g-1} \ni \frac{\tilde{C}}{y_{1} \sim q_{1}, y_{2} \sim q_{2}} \rightarrow \frac{C}{y \sim q} \in \overline{\mathcal{M}}_{g}
$$

is an admissible double cover, defined up to a sign. This ambiguity is then resolved in the choice of an element in $\operatorname{Ker}\left\{v^{*}: \operatorname{Pic}^{0}\left(C_{y q}\right)[2] \rightarrow \operatorname{Pic}^{0}(C)[2]\right\}$.

If $[C /(y \sim q, \eta), \beta]$ is a general point of $\Delta_{0}^{\prime \prime}$, then we take identical copies [ $\left.C_{1}, y_{1}, q_{1}\right]$ and $\left[C_{2}, y_{2}, q_{2}\right]$ of $[C, y, q] \in \mathcal{M}_{g-1,2}$. The Wirtinger cover is obtained by taking

$$
\overline{\mathcal{M}}_{2 g-1} \ni \frac{C_{1} \cup C_{2}}{y_{1} \sim q_{2}, y_{2} \sim q_{1}} \rightarrow \frac{C}{y \sim q} \in \overline{\mathcal{M}}_{g} .
$$

If $\left[C \cup_{\{y, q\}} E, \eta, \beta\right] \in \Delta_{0}^{\mathrm{ram}}$, then $\eta_{C} \in \sqrt{\mathcal{O}_{C}(-y-q)}$ induces a $2: 1$ cover $\tilde{C} \xrightarrow{f} C$ branched over $y$ and $q$. We set $\{\tilde{y}\}:=f^{-1}(y),\{\tilde{q}\}:=f^{-1}(q)$. The Beauville cover is

$$
\overline{\mathcal{M}}_{2 g-1} \ni \frac{\tilde{C}}{\tilde{y} \sim \tilde{q}} \rightarrow \frac{C}{y \sim q} \in \overline{\mathcal{M}}_{g}
$$

As usual, one denotes by $\delta_{0}^{\prime}, \delta_{0}^{\prime \prime}, \delta_{0}^{\mathrm{ram}}, \delta_{i}, \delta_{g-i}, \delta_{i: g-i} \in \operatorname{Pic}\left(\overline{\mathbf{R}}_{g}\right)$ the stacky divisor classes corresponding to the boundary divisors of $\overline{\mathcal{R}}_{g}$. We also set $\lambda:=\pi^{*}(\lambda) \in \operatorname{Pic}\left(\overline{\mathbf{R}}_{g}\right)$. Next we determine the canonical class $K_{\overline{\mathcal{R}}_{g}}$ :

Theorem 1.5. One has the following formula in $\operatorname{Pic}\left(\overline{\mathbf{R}}_{g}\right)$ :
$K_{\overline{\mathcal{R}}_{g}}=13 \lambda-2\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-3 \delta_{0}^{\mathrm{ram}}-2 \sum_{i=1}^{[g / 2]}\left(\delta_{i}+\delta_{g-i}+\delta_{i: g-i}\right)-\left(\delta_{1}+\delta_{g-1}+\delta_{1: g-1}\right)$.

Proof. We use that $K_{\overline{\mathcal{M}}_{g}} \equiv 13 \lambda-2 \delta_{0}-3 \delta_{1}-2 \delta_{2}-\cdots-2 \delta_{[g / 2]}$ (cf. HM$]$ ), together with the Hurwitz formula for the cover $\pi: \overline{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{M}}_{g}$. We find that $K_{\overline{\mathcal{R}}_{g}}=\pi^{*}\left(K_{\overline{\mathcal{M}}_{g}}\right)+\delta_{0}^{\mathrm{ram}}$.

Using this formula as well as the results of Section 6, we conclude that in order to prove that $\overline{\mathcal{R}}_{g}$ is of general type for a certain $g$, it suffices to exhibit a single effective divisor

$$
D \equiv a \lambda-b_{0}^{\prime} \delta_{0}^{\prime}-b_{0}^{\prime \prime} \delta_{0}^{\prime \prime}-b_{0}^{\mathrm{ram}} \delta_{0}^{\mathrm{ram}}-\sum_{i=1}^{[g / 2]}\left(b_{i} \delta_{i}+b_{g-i} \delta_{g-i}+b_{i: g-i} \delta_{i: g-i}\right) \in \operatorname{Eff}\left(\overline{\mathcal{R}}_{g}\right)
$$

satisfying the following inequalities:

$$
\begin{align*}
& \max \left\{\frac{a}{b_{0}^{\prime}}, \frac{a}{b_{0}^{\prime \prime}}\right\}<\frac{13}{2}, \quad \max \left\{\frac{a}{b_{0}^{\text {ram }}}, \frac{a}{b_{1}}, \frac{a}{b_{g-1}}, \frac{a}{b_{1: g-1}}\right\}<\frac{13}{3}, \\
& \max _{i \geq 1}\left\{\frac{a}{b_{i}}, \frac{a}{b_{g-i}}, \frac{a}{b_{i: g-i}}\right\}<\frac{13}{2} . \tag{2}
\end{align*}
$$

### 1.1. The universal Prym curve

We start by introducing the partial compactification $\widetilde{\mathcal{M}}_{g}:=\mathcal{M}_{g} \cup \widetilde{\Delta}_{0}$ of $\mathcal{M}_{g}$, obtained by adding to $\mathcal{M}_{g}$ the locus $\widetilde{\Delta}_{0} \subset \overline{\mathcal{M}}_{g}$ of one-nodal irreducible curves [ $C_{y q}:=C /(y \sim q)$ ], where $[C, y, q] \in \mathcal{M}_{g-1,2}$. Let $p: \widetilde{\mathbf{M}}_{g, 1} \rightarrow \widetilde{\mathbf{M}}_{g}$ denote the universal curve. We denote $\widetilde{\mathcal{R}}_{g}:=\pi^{-1}\left(\widetilde{\mathcal{M}}_{g}\right) \subset \overline{\mathcal{R}}_{g}$ and note that the boundary divisors $\widetilde{\Delta}_{0}^{\prime}:=\Delta_{0}^{\prime} \cap \widetilde{\mathcal{R}}_{g}, \widetilde{\Delta}_{0}^{\prime \prime}:=$ $\Delta_{0}^{\prime \prime} \cap \widetilde{\mathcal{R}}_{g}$ and $\widetilde{\Delta}_{0}^{\text {ram }}:=\Delta_{0}^{\mathrm{ram}} \cap \widetilde{\mathcal{R}}_{g}$ become disjoint inside $\widetilde{\mathcal{R}}_{g}$. Finally, we set $\mathcal{Z}:=$ $\widetilde{\mathbf{R}}_{g} \times \widetilde{\mathbf{M}}_{g} \widetilde{\mathbf{M}}_{g, 1}$ and denote by $p_{1}: \mathcal{Z} \rightarrow \widetilde{\mathbf{R}}_{g}$ the projection.

To obtain the universal family of Prym curves over $\widetilde{\mathbf{R}}_{g}$, we blow up the codimension 2 locus $V \subset \mathcal{Z}$ corresponding to points
$v=\left(\left[C \cup_{\{y, q\}} E, \eta_{C} \in \sqrt{\mathcal{O}_{C}(-y-q)}\right], \eta_{E}=\mathcal{O}_{E}(1), \nu(y)=v(q)\right) \in \Delta_{0}^{\mathrm{ram}} \times_{\widetilde{\mathbf{M}}_{g}} \widetilde{\mathbf{M}}_{g, 1}$
(recall that $v: C \rightarrow C_{y q}$ denotes the normalization map). Suppose that ( $t_{1}, \ldots, t_{3 g-3}$ ) are local coordinates in an étale neighbourhood of $\left[C \cup_{\{y, q\}} E, \eta_{C}, \eta_{E}\right] \in \widetilde{\mathcal{R}}_{g}$ such that the local equation of $\Delta_{0}^{\mathrm{ram}}$ is $\left(t_{1}=0\right)$. Then $\mathcal{Z}$ around $v$ admits local coordinates $\left(x, y, t_{1}, \ldots, t_{3 g-3}\right)$ satisfying the equation $x y=t_{1}^{2}$. In particular, $\mathcal{Z}$ is singular along $V$. We denote by $\mathcal{X}:=\operatorname{Bl}_{V}(\mathcal{Z})$ and by $f: \mathcal{X} \rightarrow \widetilde{\mathbf{R}}_{g}$ the induced family of Prym curves. Then for every $[X, \eta, \beta] \in \widetilde{\mathcal{R}}_{g}$ we have $f^{-1}([X, \eta, \beta])=X$.

On $\mathcal{X}$ there exists a Prym line bundle $\mathcal{P} \in \operatorname{Pic}(\mathcal{X})$ as well as a morphism of $\mathcal{O}_{X^{-}}$ modules $B: \mathcal{P}^{\otimes 2} \rightarrow \mathcal{O}_{\mathcal{X}}$ with the property that $\mathcal{P}_{\mid f^{-1}([X, \eta, \beta])}=\eta$ and $B_{\mid f^{-1}([X, \eta, \beta])}=$ $\beta: \eta^{\otimes 2} \rightarrow \mathcal{O}_{X}$, for all points $[X, \eta, \beta] \in \widetilde{\mathcal{R}}_{g}$ (see e.g. [C], the same argument carries over from the spin to the Prym moduli space).

We set $\mathcal{E}_{0}^{\prime}$, $\mathcal{E}_{0}^{\prime \prime}$ and $\mathcal{E}_{0}^{\text {ram }} \subset \mathcal{X}$ to be the proper transforms of the boundary divisors $p_{1}^{-1}\left(\widetilde{\Delta}_{0}^{\prime}\right), p_{1}^{-1}\left(\tilde{\Delta}_{0}^{\prime \prime}\right)$ and $p_{1}^{-1}\left(\widetilde{\Delta}_{0}^{\text {ram }}\right)$ respectively. Finally, we define $\mathcal{E}_{0}$ to be the exceptional divisor of the blow-up map $\mathcal{X} \rightarrow \mathcal{Z}$.

We recall that $g: \mathcal{Y} \rightarrow S$ is a family of nodal curves and $L, M$ are line bundles on $\mathcal{Y}$; then $\langle L, M\rangle \in \operatorname{Pic}(S)$ denotes the bilinear Deligne pairing of $L$ and $M$.

Proposition 1.6. If $f: \mathcal{X} \rightarrow \widetilde{\mathbf{R}}_{g}$ is the universal Prym curve and $\mathcal{P} \in \operatorname{Pic}(\mathcal{X})$ is the corresponding Prym bundle, then one has the following relations in $\operatorname{Pic}\left(\widetilde{\mathbf{R}}_{g}\right)$ :
(i) $\left\langle\omega_{f}, \mathcal{P}\right\rangle=0$.
(ii) $\left\langle\mathcal{O}_{\mathcal{X}}\left(\mathcal{E}_{0}\right), \mathcal{O}_{\mathcal{X}}\left(\mathcal{E}_{0}\right)\right\rangle=-2 \delta_{0}^{\mathrm{ram}}$.
(iii) $\left\langle\mathcal{O}_{\mathcal{X}}(\mathcal{P}), \mathcal{O}_{\mathcal{X}}(\mathcal{P})\right\rangle=-\delta_{0}^{\text {ram }} / 2$.

Proof. The sheaf homomorphism $B: \mathcal{P}^{\otimes 2} \rightarrow \mathcal{O}_{\mathcal{X}}$ vanishes (with order 1) precisely along the exceptional divisor $\mathcal{E}_{0}$, hence $\left[\mathcal{E}_{0}\right]=-2 c_{1}(\mathcal{P})$. Furthermore, we have the relations $f^{*}\left(\Delta_{0}^{\mathrm{ram}}\right)=\mathcal{E}_{0}^{\mathrm{ram}}+\mathcal{E}_{0}$ and $f_{*}\left(\left[\mathcal{E}_{0}^{\mathrm{ram}}\right] \cdot\left[\mathcal{E}_{0}\right]\right)=2 \delta_{0}^{\mathrm{ram}}$ (in the fibre $f^{-1}\left(\left[C \cup_{\{y, q\}} E, \eta_{C}\right]\right)$ the divisors $\mathcal{E}_{0}$ and $\mathcal{E}_{0}^{\text {ram }}$ meet over two points, corresponding to whether the marked point equals $y$ or $q$ ). Now (ii) and (iii) follow simply from the push-pull formula. For (i), it is enough to show that $\omega_{f \mid \mathcal{E}_{0}}$ is the trivial bundle. This follows because for any point $[X, \eta, \beta] \in \widetilde{\mathcal{R}}_{g}$ we have $\omega_{X} \otimes \mathcal{O}_{E}=0$ for any exceptional component $E \subset X$.
We now fix $i \geq 1$ and set $\mathcal{N}_{i}:=f_{*}\left(\omega_{f}^{\otimes i} \otimes \mathcal{P}^{\otimes i}\right)$. Since $R^{1} f_{*}\left(\omega_{f}^{\otimes i} \otimes \mathcal{P}^{\otimes i}\right)=0$, Grauert's theorem implies that $\mathcal{N}_{i}$ is a vector bundle over $\widetilde{\mathbf{R}}_{g}$ of rank $(g-1)(2 i-1)$.
Proposition 1.7. For each integer $i \geq 1$ the following formula holds in $\operatorname{Pic}\left(\widetilde{\mathbf{R}}_{g}\right)$ :

$$
c_{1}\left(\mathcal{N}_{i}\right)=\binom{i}{2}\left(12 \lambda-\delta_{0}^{\prime}-\delta_{0}^{\prime \prime}-2 \delta_{0}^{\mathrm{ram}}\right)+\lambda-\frac{i^{2}}{4} \delta_{0}^{\mathrm{ram}}
$$

Proof. We apply Grothendieck-Riemann-Roch to the universal Prym curve $f: \mathcal{X} \rightarrow \widetilde{\mathbf{R}}_{g}$ :
$c_{1}\left(\mathcal{N}_{i}\right)$

$$
=f_{*}\left[\left(1+i c_{1}\left(\omega_{f} \otimes \mathcal{P}\right)+\frac{i^{2} c_{1}^{2}\left(\omega_{f} \otimes \mathcal{P}\right)}{2}\right)\left(1-\frac{c_{1}\left(\omega_{f}\right)}{2}+\frac{c_{1}^{2}\left(\omega_{f}\right)+[\operatorname{Sing}(f)]}{12}\right)\right]_{2},
$$

and then use Proposition 1.6 and Mumford's formula $\left(\kappa_{1}\right) \widetilde{\mathbf{R}}_{g}=12 \lambda-\delta_{0}^{\prime}-\delta_{0}^{\prime \prime}-2 \delta_{0}^{\text {ram }}$.

### 1.2. Inequalities between coefficients of divisors on $\overline{\mathcal{R}}_{g}$

We use pencils of curves on $K 3$ surfaces to establish certain inequalities between the coefficients of effective divisors on $\overline{\mathcal{R}}_{g}$. Using $K 3$ surfaces we construct pencils that fill up the boundary divisors $\Delta_{i}, \Delta_{g-i}$ and $\Delta_{i: g-i}$ for $1 \leq i \leq[g / 2]$ when $g \leq 23$. The use of such pencils in the context of $\overline{\mathcal{M}}_{g}$ has already been demonstrated in [FP].

We start with a Lefschetz pencil $B \subset \overline{\mathcal{M}}_{i}$ of curves of genus $i$ lying on a fixed $K 3$ surface $S$. The pencil $B$ is induced by a family $f: \mathrm{Bl}_{i^{2}}(S) \rightarrow \mathbf{P}^{1}$ which has $i^{2}$ sections corresponding to the base points and we choose one such section $\sigma$. Using $B$, for each $g \geq i+1$ we create a genus $g$ pencil $B_{i} \subset \overline{\mathcal{M}}_{g}$ of stable curves, by gluing a fixed curve $\left[C_{2}, p\right] \in \mathcal{M}_{g-i, 1}$ along the section $\sigma$ to each member of the pencil $B$. Then we have the
following formulas on $\overline{\mathcal{M}}_{g}$ (cf. [FP Lemma 2.4]):

$$
B_{i} \cdot \lambda=i+1, \quad B_{i} \cdot \delta_{0}=6 i+18, \quad B_{i} \cdot \delta_{i}=-1, \quad B_{i} \cdot \delta_{j}=0 \text { for } j \neq i .
$$

We fix $1 \leq i \leq[g / 2]$ and lift $B_{i}$ in three different ways to pencils in $\overline{\mathcal{R}}_{g}$. First we choose a non-trivial line bundle $\eta_{2} \in \operatorname{Pic}^{0}\left(C_{2}\right)$ [2]. Let us denote by $A_{g-i} \subset \Delta_{g-i} \subset \overline{\mathcal{R}}_{g}$ the pencil of Prym curves [ $C_{2} \cup_{\sigma(\lambda)} f^{-1}(\lambda), \eta_{C_{2}}=\eta_{2}, \eta_{f^{-1}(\lambda)}=\mathcal{O}_{f^{-1}(\lambda)}$ ], with $\lambda \in \mathbf{P}^{1}$.

Next, we denote by $A_{i} \subset \Delta_{i} \subset \overline{\mathcal{R}}_{g}$ the pencil consisting of Prym curves

$$
\left[C_{2} \cup_{\sigma(\lambda)} f^{-1}(\lambda), \eta_{C_{2}}=\mathcal{O}_{C_{2}}, \eta_{f^{-1}(\lambda)} \in \overline{\operatorname{Pic}}^{0}\left(f^{-1}(\lambda)\right)[2]\right], \quad \text { where } \lambda \in \mathbf{P}^{1}
$$

Clearly $\pi\left(A_{i}\right)=B_{i}$ and $\operatorname{deg}\left(A_{i} / B_{i}\right)=2^{2 i}-1$. Finally, $A_{i: g-i} \subset \Delta_{i: g-i} \subset \overline{\mathcal{R}}_{g}$ denotes the pencil of Prym curves $\left[C_{2} \cup f^{-1}(\lambda), \eta_{C_{2}}=\eta_{2}, \eta_{f^{-1}(\lambda)} \in \overline{\operatorname{Pic}}^{0}\left(f^{-1}(\lambda)\right)[2]\right]$. Again, we have $\operatorname{deg}\left(A_{i: g-i} / B_{i}\right)=2^{2 i}-1$.

Lemma 1.8. If $A_{i}, A_{g-i}$ and $A_{i: g-i}$ are pencils defined above, we have the following relations:

- $A_{g-i} \cdot \lambda=i+1, A_{g-i} \cdot \delta_{0}^{\prime}=6 i+18, A_{g-i} \cdot \delta_{i}=A_{g-i} \cdot \delta_{0}^{\mathrm{ram}}=0$, and $A_{g-i} \cdot \delta_{g-i}=-1$.
- $A_{i} \cdot \lambda=(i+1)\left(2^{2 i}-1\right), A_{i} \cdot \delta_{0}^{\prime}=\left(2^{2 i-1}-2\right)(6 i+18), A_{i} \cdot \delta_{0}^{\prime \prime}=6 i+18$,
$A_{i} \cdot \delta_{0}^{\mathrm{ram}}=2^{2 i-2}(6 i+18)$ and $A_{i} \cdot \delta_{i}=-\left(2^{2 i}-1\right)$.
- $A_{i: g-i} \cdot \lambda=(i+1)\left(2^{2 i}-1\right), A_{i: g-i} \cdot \delta_{0}^{\prime}=\left(2^{2 i-1}-1\right)(6 i+18)$,
$A_{i: g-i} \cdot \delta_{0}^{\mathrm{ram}}=2^{2 i-2}(6 i+18), A_{i: g-i} \cdot \delta_{0}^{\prime \prime}=0$ and $A_{i: g-i} \cdot \delta_{i: g-i}=-\left(2^{2 i}-1\right)$.
Note that all these intersections are computed on $\overline{\mathcal{R}}_{g}$. The intersection numbers of $A_{i}$, $A_{g-i}$ and $A_{i: g-i}$ with the generators of $\operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right)$ not explicitly mentioned in Lemma 1.8 are all equal to 0 .

Proof. We treat in detail only the case of $A_{i}$, the other cases being similar. Using [FP] we find that $\left(A_{i} \cdot \lambda\right)_{\overline{\mathcal{R}}_{g}}=\left(\pi_{*}\left(A_{i}\right) \cdot \lambda\right)_{\overline{\mathcal{M}}_{g}}=\left(2^{2 i}-1\right)\left(B_{i} \cdot \lambda\right)_{\overline{\mathcal{M}}_{g}}$. Furthermore, since $A_{i} \cap \Delta_{g-i}=A_{i} \cap \Delta_{i: g-i}=\emptyset$, we can write the formulas

$$
\left(A_{i} \cdot \delta_{i}\right)_{\overline{\mathcal{R}}_{g}}=\left(A_{i} \cdot \pi^{*}\left(\delta_{i}\right)\right)_{\overline{\mathcal{R}}_{g}}=\left(2^{2 i}-1\right)\left(B_{i} \cdot \delta_{i}\right)_{\overline{\mathcal{M}}_{g}} .
$$

Clearly $\left(A_{i} \cdot \delta_{0}^{\prime \prime}\right)_{\overline{\mathcal{R}}_{g}}=\left(B_{i} \cdot \delta_{0}\right)_{\overline{\mathcal{M}}_{g}}=6 i+18$, whereas the intersection $A_{i} \cdot \delta_{0}^{\prime}$ corresponds to choosing an element in $\operatorname{Pic}^{0}\left(f^{-1}(\lambda)\right)[2]$, where $f^{-1}(\lambda)$ is a singular member of $B$. There are $2\left(2^{2 i-2}-1\right)(6 i+18)$ such choices.

Proposition 1.9. Let $D \equiv a \lambda-b_{0}^{\prime} \delta_{0}^{\prime}-b_{0}^{\prime \prime} \delta_{0}^{\prime \prime}-b_{0}^{\mathrm{ram}} \delta_{0}^{\mathrm{ram}}-\sum_{i=1}^{[g / 2]}\left(b_{i} \delta_{i}+b_{g-i} \delta_{g-i}+\right.$ $\left.b_{i: g-i} \delta_{i: g-i}\right) \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right)$ be the closure in $\overline{\mathcal{R}}_{g}$ of an effective divisor in $\mathcal{R}_{g}$. Then if $1 \leq$ $i \leq \min \{[g / 2], 11\}$, we have the following inequalities:
(1) $a(i+1)-b_{0}^{\prime}(6 i+18)+b_{g-i} \geq 0$.
(2) $a(i+1)-b_{0}^{\mathrm{ram}}(6 i+18) \frac{2^{2 i-2}}{2^{2 i}-1}-b_{0}^{\prime}(6 i+18) \frac{2^{2 i-1}-1}{2^{2 i}-1}+b_{i: g-i} \geq 0$.
(3) $a(i+1)-b_{0}^{\mathrm{ram}}(6 i+18) \frac{2^{2 i-2}}{2^{2 i}-1}-b_{0}^{\prime}(6 i+18) \frac{2^{2 i-1}-2}{2^{2 i}-1}-b_{0}^{\prime \prime}(6 i+18) \frac{1}{2^{2 i}-1}+b_{i} \geq 0$.

Proof. We use that in this range the pencils $A_{i}, A_{g-i}$ and $A_{i: g-i}$ fill up the boundary divisors $\Delta_{i}, \Delta_{g-i}$ and $\Delta_{i: g-i}$ respectively, hence $A_{i} \cdot D, A_{g-i} \cdot D, A_{i: g-i} \cdot D \geq 0$.

Proof of Theorem 0.8 We lift the Lefschetz pencil $B \subset \overline{\mathcal{M}}_{g}$ corresponding to a fixed $K 3$ surface to a pencil $\tilde{B} \subset \overline{\mathcal{R}}_{g}$ of Prym curves by taking Prym curves $\tilde{B}:=\left\{\left[C_{\lambda}, \eta_{C_{\lambda}}\right] \in\right.$ $\left.\overline{\mathcal{R}}_{g}:\left[C_{\lambda}\right] \in B, \eta_{C_{\lambda}} \in \overline{\operatorname{Pic}}^{0}\left(C_{\lambda}\right)[2]\right\}$. We have the following formulas:

$$
\begin{gathered}
\tilde{B} \cdot \lambda=\left(2^{2 g}-1\right)(g+1), \quad \tilde{B} \cdot \delta_{0}^{\prime}=\left(2^{2 g-1}-2\right)(6 g+18), \\
\tilde{B} \cdot \delta_{0}^{\prime \prime}=6 g+18, \quad \tilde{B} \cdot \delta_{0}^{\mathrm{ram}}=2^{2 g-2}(6 g+18) .
\end{gathered}
$$

Furthermore, $\tilde{B}$ is disjoint from all the remaining boundary classes of $\overline{\mathcal{R}}_{g}$. One now verifies that $\tilde{B} \cdot K_{\overline{\mathcal{R}}_{g}}<0$ precisely when $g \leq 7$. Since $\tilde{B}$ is a covering curve for $\overline{\mathcal{R}}_{g}$ in the range $g \leq 11, g \neq 10$, we find that $\kappa\left(\overline{\mathcal{R}}_{g}\right)=-\infty$.

## 2. Theta divisors for vector bundles and geometric loci in $\overline{\mathcal{R}}_{g}$

We present a general method of constructing geometric divisors on $\overline{\mathcal{R}}_{g}$. For a fixed point $[C, \eta] \in \mathcal{R}_{g}$ we shall study the relative position of $\eta \in \operatorname{Pic}^{0}(C)[2]$ with respect to certain pluri-theta divisors on $\mathrm{Pic}^{0}(C)$.

We start by fixing a smooth curve $C$. If $E \in U_{C}(r, d)$ is a semistable vector bundle on $C$ of integer slope $\mu(E):=d / r \in \mathbb{Z}$, then following Raynaud [ $\mathbb{R}]$, we introduce the determinantal cycle

$$
\Theta_{E}:=\left\{\eta \in \operatorname{Pic}^{g-\mu-1}(C): H^{0}(C, E \otimes \eta) \neq 0\right\} .
$$

Either $\Theta_{E}=\operatorname{Pic}^{g-\mu-1}(C)$, or else, $\Theta_{E}$ is a divisor on $\operatorname{Pic}^{g-\mu-1}(C)$ and then $\Theta_{E} \equiv r \cdot \theta$. In the latter case we say that $\Theta_{E}$ is the theta divisor of the vector bundle $E$. Clearly, $\Theta_{E}$ is a divisor if and only if $H^{0}(C, E \otimes \eta)=0$ for a general bundle $\eta \in \operatorname{Pic}^{g-\mu-1}(C)$.

Let us now fix a globally generated line bundle $L \in \operatorname{Pic}^{d}(C)$ such that $h^{0}(C, L)=$ $r+1$. The Lazarsfeld vector bundle $M_{L}$ of $L$ is defined using the exact sequence on $C$

$$
0 \rightarrow M_{L} \rightarrow H^{0}(C, L) \otimes \mathcal{O}_{C} \rightarrow L \rightarrow 0
$$

(see also [GL], [L], [V0], [F1], [FMP] for many applications of these bundles). It is customary to denote $Q_{L}:=M_{L}^{\vee}$, hence $\mu\left(Q_{L}\right)=d / r$. When $L=K_{C}$, one writes $Q_{C}:=Q_{K_{C}}$. The vector bundles $Q_{L}$ (and all its exterior powers) are semistable under mild genericity assumptions on $C$ (see [L] or [F1, Proposition 2.1]). In the case $\mu\left(\bigwedge^{i} Q_{L}\right)=g-1$, when we expect $\Theta \bigwedge^{i} Q_{L}$ to be a divisor on $\operatorname{Pic}^{0}(C)$, we may ask whether for a given point $[C, \eta] \in \mathcal{R}_{g}$ the condition $\eta \in \Theta_{\wedge^{i} Q_{L}}$ is satisfied or not. Throughout this section we denote by $\mathfrak{G}_{d}^{r} \rightarrow \mathcal{M}_{g}$ the Deligne-Mumford stack parameterizing pairs $[C, l]$, where $[C] \in \mathcal{M}_{g}$ and $l=(L, V) \in G_{d}^{r}(C)$ is a linear series of type $\mathfrak{g}_{d}^{r}$.

We fix integers $k \geq 2$ and $b \geq 0$. We set integers

$$
\begin{gathered}
i:=k b+k-b-2, \quad r:=k b+k-2, \\
g:=k(k b+k-b-2)+1=i k+1, \quad d:=k(k b+k-2) .
\end{gathered}
$$

Since $\rho(g, r, d)=0$, a general curve $[C] \in \mathcal{M}_{g}$ carries a finite number of (obviously complete) linear series $l \in G_{d}^{r}(C)$. We denote this number by

$$
N:=g!\frac{1!2!\cdots r!}{(k-1)!\cdots(k-1+r)!}=\operatorname{deg}\left(\mathfrak{G}_{d}^{r} / \mathcal{M}_{g}\right)
$$

We also note that we can write $g=(r+1)(k-1)$ and $d=r k$, and moreover each line bundle $L \in W_{d}^{r}(C)$ satisfies $h^{1}(C, L)=k-1$. Furthermore, we compute $\mu\left(\bigwedge^{i} Q_{L}\right)=$ $i k=g-1$ and then we introduce the following virtual divisor on $\mathcal{R}_{g}$ :

$$
\mathcal{D}_{g: k}:=\left\{[C, \eta] \in \mathcal{R}_{g}: \exists L \in W_{d}^{r}(C) \text { such that } h^{0}\left(C, \bigwedge^{i} Q_{L} \otimes \eta\right) \geq 1\right\}
$$

From the definition it follows that $\mathcal{D}_{g: k}$ is either pure of codimension 1 in $\mathcal{R}_{g}$, or else $\mathcal{D}_{g: k}=\mathcal{R}_{g}$. We shall prove that the second possibility does not occur.

For $[C, \eta] \in \mathcal{R}_{g}$ and $L \in W_{d}^{r}(C)$ one has the following exact sequence on $C$ :
$0 \rightarrow \bigwedge^{i} M_{L} \otimes K_{C} \otimes \eta \rightarrow \bigwedge^{i} H^{0}(C, L) \otimes K_{C} \otimes \eta \rightarrow \bigwedge^{i-1} M_{L} \otimes L \otimes K_{C} \otimes \eta \rightarrow 0$,
from which, using Serre duality, one derives the following equivalences:

$$
\begin{aligned}
{[C, \eta] } & \in \mathcal{D}_{g: k} \Leftrightarrow h^{1}\left(C, \bigwedge^{i} M_{L} \otimes K_{C} \otimes \eta\right) \geq 1 \\
& \Leftrightarrow \bigwedge^{i} H^{0}(C, L) \otimes H^{0}\left(C, K_{C} \otimes \eta\right) \rightarrow H^{0}\left(C, \bigwedge^{i-1} M_{L} \otimes L \otimes K_{C} \otimes \eta\right)
\end{aligned}
$$

is not an isomorphism.

Note that obviously $\operatorname{rank}\left(\bigwedge^{i} H^{0}(C, L) \otimes H^{0}\left(C, K_{C} \otimes \eta\right)\right)=\binom{r+1}{i}(g-1)$, while

$$
\begin{aligned}
h^{0}\left(C, \bigwedge^{i-1} M_{L} \otimes L \otimes K_{C} \otimes \eta\right) & =\chi\left(C, \bigwedge^{i-1} M_{L} \otimes L \otimes K_{C} \otimes \eta\right) \\
& =\binom{r}{i-1}(-k(i-1)+d+g-1)=\binom{r+1}{i}(g-1)
\end{aligned}
$$

(use that $M_{L}$ is a semistable vector bundle and that $\left.\mu\left(\bigwedge^{i-1} M_{L} \otimes L \otimes K_{C} \otimes \eta\right)>2 g-1\right)$.
Remark 2.1. As pointed out in the introduction, an important particular case is $k=2$, when $i=b, g=2 i+1, r=2 i, d=4 i=2 g-2$. Since $W_{2 g-2}^{g-1}(C)=\left\{K_{C}\right\}$, it follows that $[C, \eta] \in \mathcal{D}_{2 i+1,2} \Leftrightarrow \eta \in \Theta^{\wedge^{i}} Q_{C}$. The main result from [FMP] states that for any $[C] \in \mathcal{M}_{g}$ the Raynaud locus $\Theta_{\bigwedge^{i} Q_{C}}$ is a divisor in $\operatorname{Pic}^{0}(C)$ (that is, $\bigwedge^{i} Q_{C}$ has a theta divisor) and we have an equality of cycles

$$
\begin{equation*}
\Theta_{\bigwedge^{i} Q_{C}}=C_{i}-C_{i} \subset \operatorname{Pic}^{0}(C) \tag{4}
\end{equation*}
$$

where the right-hand side denotes the $i$-th difference variety of $C$, that is, the image of the difference map

$$
\phi: C_{i} \times C_{i} \rightarrow \operatorname{Pic}^{0}(C), \quad \phi(D, E):=\mathcal{O}_{C}(D-E)
$$

Using Lazarsfeld's filtration argument [L] Lemma 1.4.1], one finds that for a generic choice of distinct points $x_{1}, \ldots, x_{g-2} \in C$, there is an exact sequence

$$
0 \rightarrow \bigoplus_{l=1}^{g-2} \mathcal{O}_{C}\left(x_{l}\right) \rightarrow Q_{C} \rightarrow K_{C} \otimes \mathcal{O}_{C}\left(-x_{1}-\cdots-x_{g-2}\right) \rightarrow 0
$$

which implies the inclusion $C_{i}-C_{i} \subset \Theta_{\wedge^{i} Q_{C}}$. The importance of $[4]$ is that it shows that $\Theta_{\bigwedge^{i} Q_{C}}$ is a divisor on $\operatorname{Pic}^{0}(C)$, that is, $H^{0}\left(C, \bigwedge^{i} Q_{C} \otimes \eta\right)=0$ for a generic $\eta \in \operatorname{Pic}^{0}(C)$.

Theorem 2.2. For every genus $g=2 i+1$ we have the following identification of cycles on $\mathcal{R}_{g}$ :

$$
\mathcal{D}_{2 i+1: 2}:=\left\{[C, \eta] \in \mathcal{R}_{g}: \eta \in C_{i}-C_{i}\right\} .
$$

Next we prove that $\mathcal{D}_{g: k}$ is an actual divisor on $\mathcal{R}_{g}$ for any $k \geq 2$ and we achieve this by specialization to the $k$-gonal locus $\mathcal{M}_{g, k}^{1}$ in $\mathcal{M}_{g}$.
Theorem 2.3. Fix $k \geq 2, b \geq 1$ and $g, r, d$, $i$ defined as above. Then $\mathcal{D}_{g: k}$ is a divisor on $\mathcal{R}_{g}$. Precisely, for a generic $[C, \eta] \in \mathcal{R}_{g}$ we have $H^{0}\left(C, \bigwedge^{i} Q_{L} \otimes \eta\right)=0$ for every $L \in W_{d}^{r}(C)$.

Proof. Since there is a unique irreducible component of $\mathfrak{G}_{d}^{r}\left(\mathcal{R}_{g} / \mathcal{M}_{g}\right):=\mathfrak{G}_{d}^{r} \times \mathcal{M}_{g} \mathcal{R}_{g}$ mapping dominantly onto $\mathcal{R}_{g}$, in order to prove that $\mathcal{D}_{g: k}$ is a divisor it suffices to exhibit a single triple $[C, L, \eta] \in \mathfrak{G}_{d}^{r}\left(\mathcal{R}_{g} / \mathcal{M}_{g}\right)$ such that (1) the Petri map

$$
\mu_{0}(C, L): H^{0}(C, L) \otimes H^{0}\left(C, K_{C} \otimes L^{\vee}\right) \rightarrow H^{0}\left(C, K_{C}\right)
$$

is an isomorphism and (2) the torsion point $\eta \in \operatorname{Pic}^{0}(C)[2]$ is such that $\eta \notin \Theta^{i}{ }^{i} Q_{L}$.
Proposition 2.1.1 from [CM] ensures that for a generic $k$-gonal curve $[C, A] \in \mathfrak{G}_{k}^{1}$ of genus $g=(r+1)(k-1)$ one has $h^{0}\left(C, A^{\otimes j}\right)=j+1$ for $1 \leq j \leq r+1$. In particular there is an isomorphism $\operatorname{Sym}^{j} H^{0}(C, A) \cong H^{0}\left(C, A^{\otimes j}\right)$. Using this and Riemann-Roch, we obtain $h^{0}\left(C, K_{C} \otimes A^{\otimes(-j)}\right)=(k-1)(r+1-j)$ for $0 \leq j \leq r+1$. Thus there is a generically injective rational map $\mathfrak{G}_{k}^{1} \rightarrow \mathfrak{G}_{d}^{r}$ given by $[C, A] \mapsto\left[C, A^{\otimes r}\right]$ (The use of such a map has been first pointed out to us in a different context by S. Keel.) We claim that $\mathfrak{G}_{k}^{1}$ maps into the "main component" of $\mathfrak{G}_{d}^{r}$ which maps dominantly onto $\overline{\mathcal{M}}_{g}$. To prove this it suffices to check that the Petri map

$$
\mu_{0}\left(C, A^{\otimes r}\right): H^{0}\left(C, A^{\otimes r}\right) \otimes H^{0}\left(C, K_{C} \otimes A^{\otimes(-r)}\right) \rightarrow H^{0}\left(C, K_{C}\right)
$$

is an isomorphism (remember that $H^{0}\left(C, A^{\otimes r}\right) \cong \operatorname{Sym}^{r} H^{0}(C, A)$ ). We use the base point free pencil trick to write down the exact sequence
$0 \rightarrow H^{0}\left(K_{C} \otimes A^{\otimes-(j+1)}\right) \rightarrow H^{0}(A) \otimes H^{0}\left(K_{C} \otimes A^{\otimes(-j)}\right) \xrightarrow{\mu_{j}(A)} H^{0}\left(K_{C} \otimes A^{\otimes-(j-1)}\right)$.

One can now easily check that $\mu_{j}(A)$ is surjective for $1 \leq j \leq r$ by using the formulas $h^{0}\left(C, K_{C} \otimes A^{\otimes(-j)}\right)=(k-1)(r+1-j)$ valid for $0 \leq j \leq r+1$. This in turns implies that $\mu_{0}\left(C, A^{\otimes r}\right)$ is surjective, hence an isomorphism.

We now check condition (2) and note that for $\left[C, L=A^{\otimes r}\right] \in \mathfrak{G}_{d}^{r}$, the Lazarsfeld bundle splits as $Q_{L} \cong A^{\oplus r}$. In particular, $\bigwedge^{i} Q_{L} \cong \oplus_{\left({ }_{i}^{r}\right)} A^{\otimes i}$, hence the condition $H^{0}\left(C, \bigwedge^{i} Q_{L} \otimes \eta\right) \neq 0$ is equivalent to $H^{0}\left(C, A^{\otimes i} \otimes \eta\right) \neq 0$, that is, the translate of the theta divisor $W_{g-1}(C)-A^{\otimes i} \subset \operatorname{Pic}^{0}(C)$ cannot contain all points of order 2 on $\operatorname{Pic}^{0}(C)$. We assume by contradiction that for any $[C, A] \in \mathfrak{G}_{k}^{1}$ and any $\eta \in \operatorname{Pic}^{0}(C)[2]$, we have $H^{0}\left(C, A^{\otimes i} \otimes \eta\right) \geq 1$. We use that $\mathfrak{G}_{k}^{1}$ is irreducible and specialize $C$ to a hyperelliptic curve and choose $A=\mathfrak{g}_{2}^{1} \otimes \mathcal{O}_{C}\left(x_{1}+\cdots+x_{k-2}\right)$, with $x_{1}, \ldots, x_{k-2} \in C$ being general points. Finally we take $\eta:=\mathcal{O}_{C}\left(p_{1}+\cdots+p_{i+1}-q_{1}-\cdots-q_{i+1}\right) \in \operatorname{Pic}^{0}(C)$ [2], with $p_{1}, \ldots, p_{i+1}, q_{1}, \ldots, q_{i+1}$ being distinct ramification points of the hyperelliptic $\mathfrak{g}_{2}^{1}$. It is now straightforward to check that $H^{0}\left(C, A^{\otimes i} \otimes \eta\right)=0$.
In order to compute the class $\left[\overline{\mathcal{D}}_{g: k}\right] \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right)$ we extend the determinantal description of $\mathcal{D}_{g: k}$ to the boundary of $\overline{\mathcal{R}}_{g}$. We start by setting some notation. We denote by $\mathbf{M}_{g}^{0} \subset \mathbf{M}_{g}$ the open substack classifying curves $[C] \in \mathcal{M}_{g}$ such that $W_{d-1}^{r}(C)=\emptyset$ and $W_{d}^{r+1}(C)=\emptyset$. We know that $\operatorname{codim}\left(\mathcal{M}_{g}-\mathcal{M}_{g}^{0}, \mathcal{M}_{g}\right) \geq 2$. We further denote by $\Delta_{0}^{0} \subset \Delta_{0} \subset \overline{\mathcal{M}}_{g}$ the locus of curves $[C /(y \sim q)]$ where $[C] \in \mathcal{M}_{g-1}$ is a curve that satisfies the Brill-Noether theorem and where $y, q \in C$ are arbitrary points. Note that every Brill-Noether general curve $[C] \in \mathcal{M}_{g-1}$ satisfies

$$
W_{d-1}^{r}(C)=\emptyset, \quad W_{d}^{r+1}(C)=\emptyset \quad \text { and } \quad \operatorname{dim} W_{d}^{r}(C)=\rho(g-1, r, d)=r .
$$

We set $\overline{\mathbf{M}}_{g}^{0}:=\mathbf{M}_{g}^{0} \cup \Delta_{0}^{0} \subset \overline{\mathbf{M}}_{g}$. Then we consider the Deligne-Mumford stack

$$
\sigma_{0}: \mathfrak{G}_{d}^{r} \rightarrow \overline{\mathbf{M}}_{g}^{0}
$$

classifying pairs $[C, L]$ with $[C] \in \overline{\mathcal{M}}_{g}^{0}$ and $L \in G_{d}^{r}(C)$ (cf. [EH], [F2], [Kh]; note that it is essential that $\rho(g, r, d)=0$; at the moment there is no known extension of this stack over the entire $\overline{\mathbf{M}}_{g}$. We remark that for any curve $[C] \in \overline{\mathcal{M}}_{g}^{0}$ and $L \in W_{d}^{r}(C)$ we have $h^{0}(C, L)=r+1$, that is, $\mathfrak{G}_{d}^{r}$ parameterizes only complete linear series. Indeed, for a smooth curve $[C] \in \mathcal{M}_{g}^{0}$ we have $W_{d}^{r+1}(C)=\emptyset$, so necessarily $W_{d}^{r}(C)=G_{d}^{r}(C)$. For a point $\left[C_{y q}:=C /(y \sim q)\right] \in \Delta_{0}^{0}$ we have the identification

$$
\sigma_{0}^{-1}\left[C_{y q}\right]=\left\{L \in W_{d}^{r}(C): h^{0}\left(C, L \otimes \mathcal{O}_{C}(-y-q)\right)=r\right\}
$$

where we note that since the normalization $[C] \in \mathcal{M}_{g-1}$ is assumed to be Brill-Noether general, any sheaf $L \in \sigma_{0}^{-1}\left[C_{y q}\right]$ satisfies $h^{0}\left(C, L \otimes \mathcal{O}_{C}(-y)\right)=h^{0}\left(C, L \otimes \mathcal{O}_{C}(-q)\right)=r$ and $h^{0}(C, L)=r+1$. Furthermore, $\sigma_{0}: \mathfrak{G}_{d}^{r} \rightarrow \overline{\mathbf{M}}_{g}^{0}$ is proper, which is to say that $\bar{W}_{d}^{r}\left(C_{y q}\right)=W_{d}^{r}\left(C_{y q}\right)$, where the left-hand side denotes the closure of $W_{d}^{r}\left(C_{y q}\right)$ in the variety $\overline{\mathrm{Pic}}^{d}\left(C_{y q}\right)$ of torsion-free sheaves on $C_{y q}$. This follows because a non-locally free
torsion-free sheaf in $\bar{W}_{d}^{r}\left(C_{y q}\right)-W_{d}^{r}\left(C_{y q}\right)$ is of the form $\nu_{*}(A)$, where $A \in W_{d-1}^{r}(C)$ and $\nu: C \rightarrow C_{y q}$ is the normalization map. But we know that $W_{d-1}^{r}(C)=\emptyset$, because $[C] \in$ $\mathcal{M}_{g-1}$ satisfies the Brill-Noether theorem. Since $\rho(g, r, d)=0$, by general Brill-Noether theory, there exists a unique irreducible component of $\mathfrak{G}_{d}^{r}$ which maps onto $\overline{\mathbf{M}}_{g}^{0}$. It is certainly not the case that $\mathfrak{G}_{d}^{r}$ is irreducible, unless $k \leq 3$, when either $\mathfrak{G}_{d}^{r}=\mathbf{M}_{g}(k=2)$, or $\mathfrak{G}_{d}^{r}$ is isomorphic to a Hurwitz stack $(k=3)$. Let $f_{d}^{r}: \mathfrak{C}_{g, d}^{r}:=\overline{\mathbf{M}}_{g, 1}^{0} \times \overline{\mathbf{M}}_{g}^{0} \mathfrak{G}_{d}^{r} \rightarrow \mathfrak{G}_{d}^{r}$ denote the pullback of the universal curve $\overline{\mathbf{M}}_{g, 1}^{0} \rightarrow \overline{\mathbf{M}}_{g}^{0}$ to $\mathfrak{G}_{d}^{r}$. Once we have chosen a Poincaré bundle $\mathcal{L}$ on $\mathfrak{C}_{g, d}^{r}$ we can form the three codimension 1 tautological classes in $A^{1}\left(\mathfrak{G}_{d}^{r}\right)$ :

$$
\begin{align*}
\mathfrak{a} & :=\left(f_{d}^{r}\right)_{*}\left(c_{1}(\mathcal{L})^{2}\right), \quad \mathfrak{b}:=\left(f_{d}^{r}\right)_{*}\left(c_{1}(\mathcal{L}) \cdot c_{1}\left(\omega_{f_{d}^{r}}\right)\right), \\
\mathfrak{c} & :=\left(f_{d}^{r}\right)_{*}\left(c_{1}\left(\omega_{f_{d}^{r}}\right)^{2}\right)=\left(\sigma_{0}\right)^{*}\left(\left(\kappa_{1}\right)_{\overline{\mathbf{M}}_{g}^{0}}\right) . \tag{5}
\end{align*}
$$

These classes depend on the choice of $\mathcal{L}$ and behave functorially with respect to base change (see also Remark 2.7 for the precise statement regarding the choice of $\mathcal{L}$ ). We set $\overline{\mathbf{R}}_{g}^{0}:=\pi^{-1}\left(\widetilde{\mathbf{M}}_{g}^{0}\right) \subset \widetilde{\mathbf{R}}_{g}$ and introduce the stack of $\mathfrak{g}_{d}^{r}$,s on Prym curves

$$
\sigma: \mathfrak{G}_{d}^{r}\left(\widetilde{\mathbf{R}}_{g}^{0} / \tilde{\mathbf{M}}_{g}^{0}\right):=\overline{\mathbf{R}}_{g}^{0} \times \overline{\mathbf{M}}_{g}^{0} \mathfrak{G}_{d}^{r} \rightarrow \overline{\mathbf{R}}_{g}^{0} .
$$

By a slight abuse of notation we denote the boundary divisors by the same symbols, that is, $\Delta_{0}^{\prime}:=\sigma^{*}\left(\Delta_{0}^{\prime}\right), \Delta_{0}^{\prime \prime}:=\sigma^{*}\left(\Delta_{0}^{\prime \prime}\right)$ and $\Delta_{0}^{\mathrm{ram}}:=\sigma^{*}\left(\Delta_{0}^{\mathrm{ram}}\right)$. Finally, we introduce the universal curve over the stack of $\mathfrak{g}_{d}^{r}$ 's on Prym curves:

$$
f^{\prime}: \mathcal{X}_{d}^{r}:=\mathcal{X} \times{\overline{\mathbf{R}_{g}^{0}}} \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right) \rightarrow \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right) .
$$

On $\mathcal{X}_{d}^{r}$ there are two tautological line bundles, the universal Prym bundle $\mathcal{P}_{d}^{r}$ which is the pull-back of $\mathcal{P} \in \operatorname{Pic}(\mathcal{X})$ under the projection $\mathcal{X}_{d}^{r} \rightarrow \mathcal{X}$, and a Poincaré bundle $\mathcal{L} \in \operatorname{Pic}\left(\mathcal{X}_{d}^{r}\right)$ characterized by the property $\mathcal{L}_{\mid f^{\prime-1}[X, \eta, \beta, L]}=L \in W_{d}^{r}(C)$, for each point $[X, \eta, \beta, L] \in \mathfrak{G}_{d}^{r}\left(\overline{\mathcal{R}}_{g}^{0} / \overline{\mathcal{M}}_{g}^{0}\right)$. Note that we also have the codimension 1 classes $\mathfrak{a}, \mathfrak{b}, \mathfrak{c} \in A^{1}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right)$ defined by the formulas (5).
Proposition 2.4. Let $C$ be a curve of genus $g$ and let $L \in W_{d}^{r}(C)$ be a globally generated complete linear series. Then for any integer $0 \leq j \leq r$ and for any line bundle $A \in$ $\operatorname{Pic}^{a}(C)$ such that $a \geq 2 g+d-r+j-1$, we have $H^{1}\left(C, \bigwedge^{j} M_{L} \otimes A\right)=0$.
Proof. We use a filtration argument due to Lazarsfeld [L]. Having fixed $L$ and $A$, we choose general points $x_{1}, \ldots, x_{r-1} \in C$ such that $h^{0}\left(C, L \otimes \mathcal{O}_{C}\left(-x_{1}-\cdots-x_{r-1}\right)\right)=2$ and then there is an exact sequence on $C$

$$
0 \rightarrow L^{\vee}\left(x_{1}+\cdots+x_{r-1}\right) \rightarrow M_{L} \rightarrow \bigoplus_{l=1}^{r-1} \mathcal{O}_{C}\left(-x_{l}\right) \rightarrow 0
$$

Taking the $j$-th exterior powers and tensoring the resulting exact sequence with $A$, we find that in order to conclude that $H^{1}\left(C, \bigwedge^{i} M_{L} \otimes A\right)=0$ for $i \leq r$, it suffices to show that for $1 \leq i \leq r$ the following hold:
(1) $H^{1}\left(C, A \otimes \mathcal{O}_{C}\left(-D_{j}\right)\right)=0$ for each effective divisor $D_{j} \in C_{j}$ with support in the set $\left\{x_{1}, \ldots, x_{r-1}\right\}$,
(2) $H^{1}\left(C, A \otimes L^{\vee} \otimes \mathcal{O}_{C}\left(D_{r-j}\right)\right)=0$, for any effective divisor $D_{r-j} \in C_{r-j}$ with support contained in $\left\{x_{1}, \ldots, x_{r-1}\right\}$.
Both (1) and (2) hold for degree reasons since $\operatorname{deg}\left(C, A \otimes \mathcal{O}_{C}\left(-D_{j}\right)\right) \geq 2 g-1$ and $\operatorname{deg}\left(C, A \otimes L^{\vee} \otimes \mathcal{O}_{C}\left(D_{r-j}\right) \geq 2 g-1\right.$ and the points $x_{1}, \ldots, x_{r-1} \in C$ are general.

Next we use Proposition 2.4 to prove a vanishing result for Prym curves.
Proposition 2.5. For each point $[X, \eta, \beta, L] \in \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ and $0 \leq a \leq i-1$, we have

$$
H^{1}\left(X, \bigwedge^{a} M_{L} \otimes L^{\otimes(i-a)} \otimes \omega_{X} \otimes \eta\right)=0
$$

Proof. If $X$ is smooth, then the vanishing follows directly from Proposition 2.4. Assume now that $[X, \eta, \beta] \in \Delta_{0}^{\prime} \cup \Delta_{0}^{\prime \prime}$, that is, $\operatorname{st}(X)=X$ and $\eta \in \operatorname{Pic}^{0}(X)[2]$. As usual, we denote by $v: C \rightarrow X$ the normalization map, and $L_{C}:=v^{*}(L) \in W_{d}^{r}(C)$ satisfies $h^{0}\left(C, L_{C} \otimes \mathcal{O}_{C}(-y-q)\right)=r$, hence $H^{0}(X, L) \cong H^{0}\left(C, L_{C}\right)$, which implies that $\nu^{*}\left(M_{L}\right)=M_{L_{C}}$. Tensoring the usual exact sequence on $X$,

$$
0 \rightarrow \mathcal{O}_{X} \rightarrow v_{*} \mathcal{O}_{C} \rightarrow v_{*} \mathcal{O}_{C} / \mathcal{O}_{X} \rightarrow 0
$$

by the line bundle $\bigwedge^{a} M_{L} \otimes L^{\otimes(i-a)} \otimes \omega_{X} \otimes \eta$, we find that a sufficient condition for the vanishing $H^{1}\left(X, \bigwedge^{a} M_{L} \otimes L^{\otimes(i-a)} \otimes \omega_{X} \otimes \eta\right)=0$ to hold is that

$$
\begin{aligned}
H^{1}\left(C, \bigwedge^{a} M_{L_{C}} \otimes L_{C}^{\otimes(i-a)}\right. & \left.\otimes K_{C} \otimes \eta_{C}\right) \\
& =H^{1}\left(C, \bigwedge^{a} M_{L_{C}} \otimes L_{C}^{\otimes(i-a)} \otimes K_{C}(y+q) \otimes \eta_{C}\right)=0
\end{aligned}
$$

Since $i<r$, this follows directly from Proposition 2.4
We are left with the case when $[X, \eta, \beta] \in \Delta_{0}^{\text {ram }}$, when $X:=C \cup_{\{q, y\}} E$, with $E$ being a smooth rational curve, $L_{C} \in W_{d}^{r}(C), L_{E}=\mathcal{O}_{E}$ and $\eta_{C}^{\otimes 2}=\mathcal{O}_{C}(-y-q)$. We also have $M_{L \mid C}=M_{L_{C}}$ and $M_{L \mid E}=H^{0}\left(C, L_{C} \otimes \mathcal{O}_{C}(-y-q)\right) \otimes \mathcal{O}_{E}$. A standard argument involving the Mayer-Vietoris sequence on $X$ shows that the vanishing of the group $H^{1}\left(X, \bigwedge^{a} M_{L} \otimes L^{\otimes(i-a)} \otimes \omega_{X} \otimes \eta\right)$ is implied by the following vanishing conditions:

$$
\begin{aligned}
H^{1}\left(C, \bigwedge^{a} M_{L_{C}} \otimes L_{C}^{\otimes(i-a)} \otimes\right. & \left.K_{C}(y+q) \otimes \eta_{C}\right) \\
& =H^{1}\left(C, \bigwedge^{a} M_{L_{C}} \otimes L_{C}^{\otimes(i-a)} \otimes K_{C} \otimes \eta_{C}\right)=0
\end{aligned}
$$

The conditions of Proposition 2.4 being satisfied $(i \leq r-1)$, we finish the proof.
Proposition 2.5 enables us to define a sequence of tautological vector bundles on $\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ : First, we set $\mathcal{H}:=f_{*}^{\prime}(\mathcal{L})$. By Grauert's theorem, $\mathcal{H}$ is a vector bundle of rank $r+1$ with fibre $\mathcal{H}[X, \eta, \beta, L]=H^{0}(X, L)$. For $j \geq 0$ we set

$$
\mathcal{A}_{0, j}:=f_{*}^{\prime}\left(\mathcal{L}^{\otimes j} \otimes \omega_{f^{\prime}} \otimes \mathcal{P}_{d}^{r}\right)
$$

Since $R^{1} f_{*}^{\prime}\left(\mathcal{L}^{\otimes j} \otimes \omega_{f^{\prime}} \otimes \mathcal{P}_{d}^{r}\right)=0$ we find that $\mathcal{A}_{0, j}$ is a vector bundle over $\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ of rank equal to $h^{0}\left(X, L^{\otimes j} \otimes \omega_{X} \otimes \eta\right)=j d+g-1$. Next we introduce the global Lazarsfeld vector bundle $\mathcal{M}$ over $\mathcal{X}_{d}^{r}$ by the exact sequence

$$
0 \rightarrow \mathcal{M} \rightarrow f^{\prime *}(\mathcal{H}) \rightarrow \mathcal{L} \rightarrow 0
$$

hence $\mathcal{M}_{f^{\prime-1}[X, \eta, \beta, L]}=M_{L}$ for each $[X, \eta, \beta, L] \in \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$. Then for integers $a, j \geq 1$ we define the sheaf

$$
\mathcal{A}_{a, j}:=f_{*}^{\prime}\left(\bigwedge^{a} \mathcal{M} \otimes \mathcal{L}^{\otimes j} \otimes \omega_{f^{\prime}} \otimes \mathcal{P}_{d}^{r}\right)
$$

For each $1 \leq a \leq i-1$, we have proved that $R^{1} f_{*}^{\prime}\left(\bigwedge^{a} \mathcal{M} \otimes \mathcal{L}^{\otimes(i-a)} \otimes \omega_{f^{\prime}} \otimes \mathcal{P}_{d}^{r}\right)=0$ (cf. Proposition 2.5, therefore $\mathcal{A}_{a, i-a}$ is a vector bundle over $\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ having rank

$$
\operatorname{rk}\left(\mathcal{A}_{a, i-a}\right)=\chi\left(X, \bigwedge^{a} M_{L} \otimes L^{\otimes(i-a)} \otimes \omega_{X} \otimes \eta\right)=\binom{r}{a} k(i-a)(r+1)
$$

Proposition 2.5 also shows that for all integers $1 \leq a \leq i-1$, the vector bundles $\mathcal{A}_{a, i-a}$ sit in exact sequences

$$
\begin{equation*}
0 \rightarrow \mathcal{A}_{a, i-a} \rightarrow \bigwedge^{a} \mathcal{H} \otimes \mathcal{A}_{0, i-a} \rightarrow \mathcal{A}_{a-1, i-a+1} \rightarrow 0 \tag{6}
\end{equation*}
$$

We shall need the expression for the Chern numbers of $\mathcal{A}_{a, i-a}$. Using 6] it will be sufficient to compute $c_{1}\left(\mathcal{A}_{0, j}\right)$ for all $j \geq 0$.

Proposition 2.6. For all $j \geq 0$ one has the following formula in $A^{1}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right)$ :

$$
c_{1}\left(\mathcal{A}_{0, j}\right)=\lambda+\frac{j}{2} B+\frac{j^{2}}{2} A-\frac{1}{4} \delta_{0}^{\mathrm{ram}}
$$

Proof. We apply Grothendieck-Riemann-Roch to the morphism $f^{\prime}: \mathcal{X}_{d}^{r} \rightarrow \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ :

$$
\begin{aligned}
c_{1}\left(\mathcal{A}_{0, j}\right)= & c_{1}\left(f_{!}^{\prime}\left(\omega_{f^{\prime}} \otimes \mathcal{L}^{\otimes j} \otimes \mathcal{P}_{d}^{r}\right)\right) \\
= & f_{*}^{\prime}\left[\left(1+c_{1}\left(\omega_{f^{\prime}} \otimes \mathcal{L}^{\otimes j} \otimes \mathcal{P}_{d}^{r}\right)+\frac{c_{1}^{2}\left(\omega_{f^{\prime}} \otimes \mathcal{L}^{\otimes j} \otimes \mathcal{P}_{d}^{r}\right)}{2}\right)\right. \\
& \left.\cdot\left(1-\frac{c_{1}\left(\omega_{f^{\prime}}\right)}{2}+\frac{c_{1}^{2}\left(\omega_{f^{\prime}}\right)+\left[\operatorname{Sing}\left(f^{\prime}\right)\right]}{12}\right)\right]_{2}
\end{aligned}
$$

where $\operatorname{Sing}\left(f^{\prime}\right) \subset \mathcal{X}_{d}^{r}$ denotes the codimension 2 singular locus of the morphism $f^{\prime}$, therefore $f_{*}^{\prime}\left[\operatorname{Sing}\left(f^{\prime}\right)\right]=\Delta_{0}^{\prime}+\Delta_{0}^{\prime \prime}+2 \Delta_{0}^{\mathrm{ram}}$. We finish the proof using Mumford's formula $\kappa_{1}=f_{*}^{\prime}\left(c_{1}^{2}\left(\omega_{f^{\prime}}\right)\right)=12 \lambda-\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}+2 \delta_{0}^{\mathrm{ram}}\right)$ and noting that $f_{*}^{\prime}\left(c_{1}(\mathcal{L})\right.$. $\left.c_{1}\left(\mathcal{P}_{d}^{r}\right)\right)=0$ (the restriction of $\mathcal{L}$ to the exceptional divisor of $f^{\prime}: \mathcal{X}_{d}^{r} \rightarrow \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ is trivial) and $f_{*}^{\prime}\left(c_{1}\left(\omega_{f^{\prime}}\right) \cdot c_{1}\left(\mathcal{P}_{d}^{r}\right)\right)=0$. Finally, according to Proposition 1.6 we have $f_{*}^{\prime}\left(c_{1}^{2}\left(\mathcal{P}_{d}^{r}\right)\right)=-\delta_{0}^{\mathrm{ram}} / 2$.

Remark 2.7. While the construction of the vector bundles $\mathcal{A}_{a, j}$ depends on the choice of the Poincaré bundle $\mathcal{L}$ and that of the Prym bundle $\mathcal{P}_{d}^{r}$, it is easy to check that if we set the vector bundles $\mathcal{A}:=\bigwedge^{i} \mathcal{H} \otimes \mathcal{A}_{0,0}$ and $\mathcal{B}:=\mathcal{A}_{i-1, i}$, then the vector bundle $\operatorname{Hom}(\mathcal{A}, \mathcal{B})$ on $\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$, as well as the morphism

$$
\phi \in H^{0}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right), \operatorname{Hom}(\mathcal{A}, \mathcal{B})\right)
$$

whose degeneracy locus is the virtual divisor $\overline{\mathcal{D}}_{g: k}$, are independent of such choices. More precisely, let us denote by $\Xi$ the collection of triples $\alpha:=\left(\pi_{\alpha}, \mathcal{L}_{\alpha},\left(\mathcal{P}_{d}^{r}\right)_{\alpha}\right)$, where $\pi_{\alpha}: \Sigma_{\alpha} \rightarrow \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ is an étale surjective morphism from a scheme $\Sigma_{\alpha},\left(\mathcal{P}_{d}^{r}\right)_{\alpha}$ is a Prym bundle and $\mathcal{L}_{\alpha}$ is a Poincaré bundle on $p_{2, \alpha}: \mathcal{X}_{d}^{r} \times_{\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)} \Sigma_{\alpha} \rightarrow \Sigma_{\alpha}$. Recall that if $\Sigma \rightarrow \mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ is an étale surjection from a scheme and $\mathcal{L}$ and $\mathcal{L}^{\prime}$ are two Poincaré bundles on $p_{2}: \mathcal{X}_{d}^{r} \times_{\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)} \Sigma \rightarrow \Sigma$, then the sheaf $\mathcal{N}:=p_{2 *} \operatorname{Hom}\left(\mathcal{L}, \mathcal{L}^{\prime}\right)$ is invertible and there is a canonical isomorphism $\mathcal{L} \otimes p_{2}^{*} \mathcal{N} \cong \mathcal{L}^{\prime}$. For every $\alpha \in \Xi$ we construct the morphism between vector bundles of the same rank $\phi_{\alpha}: \mathcal{A}_{\alpha} \rightarrow \mathcal{B}_{\alpha}$ as above. Then since a straightforward cocycle condition is met, we find that there exists a vector bundle $\operatorname{Hom}(\mathcal{A}, \mathcal{B})$ on $\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$ together with a section $\phi \in H^{0}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right), \operatorname{Hom}(\mathcal{A}, \mathcal{B})\right)$ such that for every $\alpha=\left(\pi_{\alpha}, \mathcal{L}_{\alpha},\left(\mathcal{P}_{d}^{r}\right)_{\alpha}\right) \in \Xi$ we have

$$
\pi_{\alpha}^{*}(\operatorname{Hom}(\mathcal{A}, \mathcal{B}))=\operatorname{Hom}\left(\mathcal{A}_{\alpha}, \mathcal{B}_{\alpha}\right) \quad \text { and } \quad \pi_{\alpha}^{*}(\phi)=\phi_{\alpha} .
$$

We are finally in a position to compute the class of the divisor $\overline{\mathcal{D}}_{g: k}$.
Theorem 2.8. Fix integers $k \geq 2, b \geq 0$ and set $i:=k b-b+k-2, r:=k b+k-2, g:=$ $i k+1, d:=r k$ as above. Then there exists a morphism $\phi: \bigwedge^{i} \mathcal{H} \otimes \mathcal{A}_{0,0} \rightarrow \mathcal{A}_{i-1,1}$ between vector bundles of the same rank over $\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)$, such that the push-forward under $\sigma$ of the restriction to $\mathfrak{G}_{d}^{r}\left(\mathbf{R}_{g}^{0} / \boldsymbol{M}_{g}^{0}\right)$ of the degeneration locus of $\phi$ is precisely the effective divisor $\mathcal{D}_{g: k}$. Moreover we have the following expression for its class in $A^{1}\left(\overline{\mathbf{R}}_{g}^{0}\right)$ :

$$
\begin{aligned}
\sigma_{*}\left(c _ { 1 } \left(\mathcal{A}_{i-1,1}\right.\right. & \left.\left.-\bigwedge^{i} \mathcal{H} \otimes \mathcal{A}_{0,0}\right)\right) \\
\equiv & \equiv\binom{r}{b} \frac{N}{(r+k)}(k r+k-r-3)\left(\mathfrak{A} \lambda-\frac{\mathfrak{B}_{0}}{6}\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-\frac{\mathfrak{B}_{0}^{\mathrm{ram}}}{12} \delta_{0}^{\mathrm{ram}}\right),
\end{aligned}
$$

where

$$
\begin{aligned}
\mathfrak{A}= & \left(k^{5}-4 k^{4}+5 k^{3}-2 k^{2}\right) b^{3}+\left(3 k^{5}-13 k^{4}+24 k^{3}-23 k^{2}+9 k\right) b^{2} \\
& +\left(3 k^{5}-14 k^{4}+34 k^{3}-45 k^{2}+24 k-4\right) b+k^{5}-5 k^{4}+15 k^{3}-25 k^{2}+16 k-2, \\
\mathfrak{B}_{0}= & \left(k^{5}-4 k^{4}+5 k^{3}-2 k^{2}\right) b^{3}+\left(3 k^{5}-13 k^{4}+22 k^{3}-17 k^{2}+5 k\right) b^{2} \\
& +\left(3 k^{5}-14 k^{4}+30 k^{3}-33 k^{2}+14 k-2\right) b+k^{5}-5 k^{4}+13 k^{3}-19 k^{2}+10 k
\end{aligned}
$$

and

$$
\begin{aligned}
& \mathfrak{B}_{0}^{\mathrm{ram}}=\left(4 k^{5}-16 k^{4}+20 k^{3}-8 k^{2}\right) b^{3}+\left(12 k^{5}-52 k^{4}+85 k^{3}-65 k^{2}+20 k\right) b^{2} \\
& +\left(12 k^{5}-56 k^{4}+111 k^{3}-114 k^{2}+53 k-8\right) b+4 k^{5}-20 k^{4}+46 k^{3}-58 k^{2}+34 k-6 .
\end{aligned}
$$

Proof. To compute the class of the degeneracy locus of $\phi$ we use the exact sequence (6) and Proposition 2.6. We write the following identities in $A^{1}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right)$ :

$$
\begin{aligned}
& c_{1}\left(\mathcal{A}_{i-1,1}-\bigwedge^{i} \mathcal{H} \otimes \mathcal{A}_{0,0}\right)=\sum_{l=0}^{i}(-1)^{l-1} c_{1}\left(\bigwedge^{i-l} \mathcal{H} \otimes \mathcal{A}_{0, l}\right) \\
&= \sum_{l=0}^{i}(-1)^{l-1}\left((l d+g-1)\binom{r}{i-l-1} c_{1}(\mathcal{H})+\binom{r+1}{i-l} c_{1}\left(\mathcal{A}_{0, l}\right)\right) \\
&=-k\binom{k b+k-4}{b-1} c_{1}(\mathcal{H})+\frac{1}{2}\binom{k b+k-3}{b} \mathfrak{b} \\
&-\binom{k b+k-2}{b} \lambda-\frac{k b+k-2 b-3}{2(k b+k-3)}\binom{k b+k-3}{b} \mathfrak{a}+\frac{1}{4}\binom{k b+k-2}{b} \delta_{0}^{\mathrm{ram}} \\
&=\binom{r-1}{b}\left(-\frac{k b}{r-1} c_{1}(\mathcal{H})+\frac{1}{2} \mathfrak{b}-\frac{r-2 b-1}{2(r-1)} \mathfrak{a}-\frac{r}{r-b} \lambda+\frac{r}{4(r-b)} \delta_{0}^{\mathrm{ram}}\right)
\end{aligned}
$$

where $\delta_{0}^{\mathrm{ram}}=\sigma^{*}\left(\delta_{0}^{\mathrm{ram}}\right) \in A^{1}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right)$. The classes $\mathfrak{a}, \mathfrak{b} \in A^{1}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right)$ and the line bundle $\mathcal{H} \in \operatorname{Pic}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right)$ are defined in terms of a Poincaré bundle $\mathcal{L}$ : If $\mathcal{L}^{\prime}:=\mathcal{L} \otimes f^{\prime *}(\mathcal{M})$ is another Poincaré bundle with $\mathcal{M} \in \operatorname{Pic}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right)$ and if $\mathfrak{a}^{\prime}, \mathfrak{b}^{\prime}, \mathcal{H}^{\prime}$ denote the classes defined in terms of $\mathcal{L}^{\prime}$ using 5 , then we have the formulas
$\mathfrak{a}^{\prime}=\mathfrak{a}+2 d c_{1}(\mathcal{M}), \quad \mathfrak{b}^{\prime}=\mathfrak{b}+(2 g-2) c_{1}(\mathcal{M}), \quad c_{1}\left(\mathcal{H}^{\prime}\right)=c_{1}(\mathcal{H})+(r+1) c_{1}(\mathcal{M})$.
A straightforward calculation shows that the class

$$
\begin{equation*}
\Xi:=-\frac{k b}{r-1} c_{1}(\mathcal{H})+\frac{1}{2} \mathfrak{b}-\frac{r-2 b-1}{2(r-1)} \mathfrak{a} \in A^{1}\left(\mathfrak{G}_{d}^{r}\left(\overline{\mathbf{R}}_{g}^{0} / \overline{\mathbf{M}}_{g}^{0}\right)\right) \tag{7}
\end{equation*}
$$

is independent of the choice of $\mathcal{L}$ and $\sigma_{*}(\Xi)=\pi^{*}\left(\left(\sigma_{0}\right)_{*}\left(\Xi_{0}\right)\right)$, where the $\Xi_{0} \in A^{1}\left(\mathfrak{G}_{d}^{r}\right)$ is defined by the same formula (7) but inside $\operatorname{Pic}\left(\mathfrak{G}_{d}^{r}\right)$. We outline below the computation of $\pi^{*}\left(\left(\sigma_{0}\right)_{*}\left(\Xi_{0}\right)\right)$, which uses [F2] in an essential way.

We follow closely [F2] and denote by $\overline{\mathbf{M}}_{g}^{1}:=\mathbf{M}_{g}^{0} \cup \Delta_{0}^{0} \cup \Delta_{1}^{0}$ the partial compactification of $\mathbf{M}_{g}^{0}$ obtained from $\overline{\mathbf{M}}_{g}^{0}$ by adding the stack $\Delta_{1}^{0} \subset \Delta_{1}$ consisting of curves $[C \cup y E]$, where $[C, y] \in \mathcal{M}_{g-1,1}$ is a Brill-Noether general pointed curve and $[E, y] \in \overline{\mathcal{M}}_{1,1}$. We extend $\sigma_{0}: \mathfrak{G}_{d}^{r} \rightarrow \overline{\mathbf{M}}_{g}^{0}$ to a proper map $\sigma_{1}: \widetilde{\mathfrak{G}}_{d}^{r} \rightarrow \overline{\mathbf{M}}_{g}^{1}$ from the Deligne-Mumford stack of limit linear series $\mathfrak{q}_{d}^{r}$ (cf. [EH], [F2], [Kh]). Then for each $n \geq 1$ we consider the vector bundles $\mathcal{G}_{0, n}$ over $\widetilde{\mathfrak{G}}_{d}^{r}$ defined in [F2, Proposition 2.8] with the following description of their fibres:

- $\mathcal{G}_{0, n}(C, L)=H^{0}\left(C, L^{\otimes n}\right)$ for each $[C] \in \mathcal{M}_{g}^{0}$ and $L \in W_{d}^{r}(C)$.
- $\mathcal{G}_{0, n}(t)=H^{0}\left(C, L^{\otimes n}(-y-q)\right) \oplus \mathbb{C} \cdot u^{n} \subset H^{0}\left(C, L^{\otimes n}\right)$, where $t=\left(C_{y q}, L \in\right.$ $\left.W_{d}^{r}(C)\right) \in \sigma_{0}^{-1}\left(\left[C_{y q}\right]\right)$ with $u \in H^{0}(C, L)$ being a section such that

$$
H^{0}(C, L)=H^{0}(C, L(-y-q)) \oplus \mathbb{C} \cdot u
$$

- $\mathcal{G}_{0, n}(t)=H^{0}\left(C, L^{\otimes n}(-2 y)\right) \oplus \mathbb{C} \cdot u^{n} \subset H^{0}\left(C, L^{\otimes n}\right)$, where $t=\left(C \cup_{y} E, l_{C}, l_{E}\right) \in$ $\sigma_{0}^{-1}\left(\left[C \cup_{y} E\right]\right)$ and $\left(l_{C}, l_{E}\right) \in G_{d}^{r}(C) \times G_{d}^{r}(E)$ is a limit linear series $\mathfrak{g}_{d}^{r}$ with $l_{C}=$ $\left(L, H^{0}(C, L)\right)$ and $u \in H^{0}(C, L)$ a section such that

$$
H^{0}(C, L)=H^{0}(C, L(-2 y)) \oplus \mathbb{C} \cdot u .
$$

We extend the classes $\mathfrak{a}, \mathfrak{b} \in A^{1}\left(\mathfrak{G}_{d}^{r}\right)$ over the stack $\widetilde{\mathfrak{G}}_{d}^{r}$ by choosing a Poincaré bundle over $\overline{\mathbf{M}}_{g, 1}^{1} \times{\overline{\mathbf{M}_{g}^{1}}} \widetilde{\mathfrak{G}}_{d}^{r}$ which restricts to line bundles of bidegree $(d, 0)$ on curves [ $C \cup_{y} E$ ] $\in \Delta_{1}^{0}$. Grothendieck-Riemann-Roch applied to the universal curve over $\widetilde{\mathfrak{G}}_{d}^{r}$ gives that

$$
\begin{equation*}
c_{1}\left(\mathcal{G}_{0, n}\right)=\lambda-\frac{n}{2} \mathfrak{b}+\frac{n^{2}}{2} \mathfrak{a} \in A^{1}\left(\widetilde{\mathfrak{G}}_{d}^{r}\right) \quad \text { for all } n \geq 2 \tag{8}
\end{equation*}
$$

while obviously $\sigma^{*}\left(\mathcal{G}_{0,1}\right)=\mathcal{H}$. We now fix a general pointed curve $[C, q] \in \mathcal{M}_{g-1}$ and an elliptic curve $[E, y] \in \mathcal{M}_{1,1}$ and consider the test curves (see also [F2] p. 7])

$$
C^{0}:=\{C /(y \sim q)\}_{y \in C} \subset \Delta_{0}^{0} \subset \overline{\mathcal{M}}_{g}^{1} \quad \text { and } \quad C^{1}:=\left\{C \cup_{y} E\right\}_{y \in C} \subset \Delta_{1}^{0} \subset \overline{\mathcal{M}}_{g}^{1}
$$

For $n \geq 1$, the intersection numbers $C^{0} \cdot\left(\sigma_{0}\right)_{*}\left(c_{1}\left(\mathcal{G}_{0, n}\right)\right)$ and $C^{1} \cdot\left(\sigma_{0}\right)_{*}\left(c_{1}\left(\mathcal{G}_{0, n}\right)\right)$ can be computed using [F2], Lemmas 2.6 and 2.13 and Proposition 2.12]. Together with the relation (cf. [F2, p. 15] for details)

$$
\left(\sigma_{0}\right)_{*}\left(c_{1}\left(\mathcal{G}_{0, n}\right)\right)_{\lambda}-12\left(\sigma_{0}\right)_{*}\left(c_{1}\left(\mathcal{G}_{0, n}\right)\right)_{\delta_{0}}+\left(\sigma_{0}\right)_{*}\left(c_{1}\left(\mathcal{G}_{0, n}\right)\right)_{\delta_{1}}=0,
$$

this completely determines the classes $\left(\sigma_{0}\right)_{*}\left(c_{1}\left(\mathcal{G}_{0, n}\right)\right) \in A^{1}\left(\widetilde{\mathfrak{G}}_{d}^{r}\right)$. Then using 8 we find

$$
\begin{aligned}
\left(\sigma_{0}\right)_{*}(\mathfrak{a}) \equiv & N\left(-\frac{r k\left(r^{2} k^{2}-3 r^{2} k+3 r k^{2}+2 r^{2}+2 k^{2}+4 k-7 r k-4 r-10\right)}{(r k-r+k-3)(r k-r+k-2)} \lambda\right. \\
& \left.+\frac{r k\left(r^{2} k^{2}-3 r^{2} k+3 r k^{2}-8 r k+2 r^{2}+2 k^{2}+r-k-3\right)}{6(r k-r+k-3)(r k-r+k-2)} \delta_{0}+\cdots\right), \\
\left(\sigma_{0}\right)_{*}(\mathfrak{b}) \equiv & N\left(\frac{6 r k}{r k-r+k-2} \lambda-\frac{r k}{2(r k-r+k-2)} \delta_{0}+\cdots\right)
\end{aligned}
$$

this completes the computation of the class $\left(\sigma_{0}\right)_{*}(\Xi)$ and finishes the proof.
The rather unwieldy expressions from Theorem 2.8 simplify nicely for $k=2$, 3 when we obtain Theorems 0.2 and 0.3

Proof of Theorem 0.1 when $g=2 i+1$. We construct an effective divisor on $\overline{\mathcal{R}}_{g}$ satisfying the inequalities 2 as follows: The pull-back to $\overline{\mathcal{R}}_{g}$ of the Harris-Mumford divisor $\overline{\mathcal{M}}_{g, i+1}^{1}$ of curves of genus $2 i+1$ with a $\mathfrak{g}_{i+1}^{1}$ is given by the formula

$$
\begin{aligned}
& \pi^{*}\left(\overline{\mathcal{M}}_{g, i+1}^{1}\right) \equiv \frac{(2 i-2)!}{(i+1)!(i-1)!} \\
& \quad \times\left(6(i+2) \lambda-(i+1)\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}+2 \delta_{0}^{\mathrm{ram}}\right)-\sum_{j=1}^{i} 3 j(g-j)\left(\delta_{j}+\delta_{g-j}+\delta_{j: g-j}\right)\right) .
\end{aligned}
$$

We split $\overline{\mathcal{D}}_{2 i+1: 2}$ into boundary components of compact type and their complement,

$$
\overline{\mathcal{D}}_{2 i+1: 2} \equiv E+\sum_{j=1}^{i}\left(a_{j} \delta_{j}+a_{g-j} \delta_{g-j}+a_{j: g-j} \delta_{j: g-j}\right)
$$

where $a_{j}, a_{g-j}, a_{j: g-j} \geq 0$ and $\Delta_{j}, \Delta_{g-j}, \Delta_{j: g-j} \nsubseteq \operatorname{supp}(E)$ for $1 \leq j \leq i$, and we consider the following positive linear combination on $\overline{\mathcal{R}}_{g}$ :

$$
\begin{aligned}
A & :=\frac{i!(i-1)!}{(2 i-1)(2 i-3)!} \cdot \pi^{*}\left(\overline{\mathcal{M}}_{2 i+1, i+1}^{1}\right)+4 \frac{(i!)^{2}}{(2 i)!} \cdot E \\
& \equiv \frac{4(3 i+5)}{i+1} \lambda-2\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-3 \delta_{0}^{\mathrm{ram}}-\cdots
\end{aligned}
$$

where each of the coefficients of $\delta_{j}, \delta_{g_{-j}}$ and $\delta_{j: g-j}$ in the expansion of $A$ is at least

$$
\frac{6(i-1) j(2 i+1-j)}{(2 i-1)(i+1)} \geq 2
$$

Since $\frac{4(3 i+5)}{i+1}<13$ for $i \geq 8$, the conclusion now follows using 22. For $i=7$ we find that $A \equiv 13 \lambda-2\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-3 \delta_{0}^{\text {ram }}-\cdots$, hence $\kappa\left(\overline{\mathcal{R}}_{15}\right) \geq 0$. To obtain $\kappa\left(\overline{\mathcal{R}}_{15}\right) \geq 1$, we use the fact that on $\overline{\mathcal{M}}_{15}$ there exists a Brill-Noether divisor other than $\overline{\mathcal{M}}_{15,8}^{1}$, namely the divisor $\overline{\mathcal{M}}_{15,14}^{3}$ of curves $[C] \in \mathcal{M}_{15}$ with a $\mathfrak{g}_{14}^{3}$. This divisor has the same slope $s\left(\overline{\mathcal{M}}_{15,14}^{3}\right)=s\left(\overline{\mathcal{M}}_{15,8}^{1}\right)=27 / 4$, but $\operatorname{supp}\left(\overline{\mathcal{M}}_{15,14}^{3}\right) \neq \operatorname{supp}\left(\overline{\mathcal{M}}_{15,8}^{1}\right)$. It follows that there exist constants $\alpha, \beta, \gamma, m \in \mathbb{Q}>0$ such that

$$
\alpha \cdot E+\beta \cdot \pi^{*}\left(\overline{\mathcal{M}}_{15,8}^{1}\right) \equiv \alpha \cdot E+\gamma \cdot \pi^{*}\left(\overline{\mathcal{M}}_{15,14}^{3}\right) \in\left|m K_{\overline{\mathcal{R}}_{15}}\right| .
$$

Thus we have found distinct multicanonical divisors on $\overline{\mathcal{M}}_{15}$, that is, $\kappa\left(\overline{\mathcal{M}}_{15}\right) \geq 1$.
Remark 2.9. The same numerical argument shows that if one replaces $\overline{\mathcal{M}}_{15,8}^{1}$ with any divisor $D \in \operatorname{Eff}\left(\overline{\mathcal{M}}_{15}\right)$ with $s(D)<s\left(\overline{\mathcal{M}}_{15,8}^{1}\right)=27 / 4$, then $\overline{\mathcal{R}}_{15}$ is of general type. Any counterexample to the Slope Conjecture on $\overline{\mathcal{M}}_{15}$ makes $\overline{\mathcal{R}}_{15}$ of general type.

## 3. Koszul cohomology of Prym canonical curves

We recall that for a curve $C$, a line bundle $L \in \operatorname{Pic}^{d}(C)$ and integers $i, j \geq 0$, the Koszul cohomology group $K_{i, j}(C, L)$ is obtained from the complex

$$
\begin{aligned}
& \bigwedge^{i+1} H^{0}(L) \otimes H^{0}\left(L^{\otimes(j-1)}\right) \xrightarrow{d_{i+1, j-1}} \bigwedge^{i} H^{0}(L) \otimes H^{0}\left(L^{\otimes j}\right) \\
& \xrightarrow{d_{i, j}} \\
& \bigwedge^{i-1} H^{0}(L) \otimes H^{0}\left(L^{\otimes(j+1)}\right),
\end{aligned}
$$

where the maps are the Koszul differentials (cf. [GL]). There is a well-known connection between Koszul cohomology groups and Lazarsfeld bundles. Assuming that $L$ is globally generated, a diagram chasing argument involving exact sequences of the type

$$
0 \rightarrow \bigwedge^{a} M_{L} \otimes L^{\otimes b} \rightarrow \bigwedge^{a} H^{0}(L) \otimes L^{\otimes b} \rightarrow \bigwedge^{a-1} M_{L} \otimes L^{\otimes(b+1)} \rightarrow 0
$$

for various $a, b \geq 0$, yields the following identification (see also [GL, Lemma 1.10]):

$$
\begin{equation*}
K_{i, j}(C, L)=\frac{H^{0}\left(C, \bigwedge^{i} M_{L} \otimes L^{\otimes j}\right)}{\operatorname{Image}\left\{\bigwedge^{i+1} H^{0}(C, L) \otimes H^{0}\left(C, L^{\otimes(j-1)}\right)\right\}} \tag{9}
\end{equation*}
$$

We fix $[C, \eta] \in \mathcal{R}_{g}$, set $L:=K_{C} \otimes \eta \in W_{2 g-2}^{g-2}(C)$ and consider the Prym-canonical map $C \xrightarrow{|L|} \mathbf{P}^{g-2}$. We denote by $\mathcal{I}_{C} \subset \mathcal{O}_{\mathbf{P}^{g-2}}$ the ideal sheaf of the Prym-canonical curve.

By analogy with [F2] we study the Koszul stratification of $\mathcal{R}_{g}$ and define the strata

$$
\mathcal{U}_{g, i}:=\left\{[C, \eta] \in \mathcal{R}_{g}: K_{i, 2}\left(C, K_{C} \otimes \eta\right) \neq \emptyset\right\} .
$$

Using (9) we write the series of equivalences

$$
\begin{aligned}
{[C, \eta] \in \mathcal{U}_{g, i} } & \Leftrightarrow H^{1}\left(C, \bigwedge^{i+1} M_{L} \otimes L\right) \neq \emptyset \\
& \Leftrightarrow h^{0}\left(C, \bigwedge^{i+1} M_{L} \otimes L\right)>\binom{g-2}{i+1}\left(-\frac{(i+1)(2 g-2)}{g-2}+(g-1)\right) .
\end{aligned}
$$

Next we write down the exact sequence

$$
0 \rightarrow H^{0}\left(\bigwedge^{i+1} M_{\mathbf{P}^{g-2}}(1)\right) \xrightarrow{a} H^{0}\left(C, \bigwedge^{i+1} M_{L} \otimes L\right) \rightarrow H^{1}\left(\bigwedge^{i+1} M_{\mathbf{P}^{g-2}} \otimes \mathcal{I}_{C}(1)\right) \rightarrow 0
$$

and then also

$$
\operatorname{Coker}(a)=H^{1}\left(\mathbf{P}^{g-2}, \bigwedge^{i+1} M_{\mathbf{P}^{g-2}} \otimes \mathcal{I}_{C}(1)\right)=H^{0}\left(\mathbf{P}^{g-2}, \bigwedge^{i} M_{\mathbf{P}^{g-2}} \otimes \mathcal{I}_{C}(2)\right)
$$

Using the well-known fact that $h^{0}\left(\mathbf{P}^{g-2}, \bigwedge^{i+1} M_{\mathbf{P}^{g-2}}(1)\right)=\binom{g-1}{i+2}$ (use for instance the Bott vanishing theorem), we end up with the following equivalence:

$$
\begin{equation*}
[C, \eta] \in \mathcal{U}_{g, i} \Leftrightarrow h^{0}\left(\mathbf{P}^{g-2}, \bigwedge^{i} M_{\mathbf{P}^{g-2}} \otimes \mathcal{I}_{C}(2)\right)>\binom{g-3}{i} \frac{(g-1)(g-2 i-6)}{i+2} . \tag{10}
\end{equation*}
$$

Proposition 3.1. (1) For $g<2 i+6$, we have $K_{i, 2}\left(C, K_{C} \otimes \eta\right) \neq \emptyset$ for any $[C, \eta] \in \mathcal{R}_{g}$, that is, the Prym-canonical curve $C \xrightarrow{\left|K_{C}+\eta\right|} \mathbf{P}^{g-2}$ does not satisfy property $\left(N_{i}\right)$.
(2) For $g=2 i+6$, the locus $\mathcal{U}_{g, i}$ is a virtual divisor on $\mathcal{R}_{g}$, that is, there exist vector bundles $\mathcal{G}_{i, 2}$ and $\mathcal{H}_{i, 2}$ over $\mathbf{R}_{g}$ such that $\operatorname{rank}\left(\mathcal{G}_{i, 2}\right)=\operatorname{rank}\left(\mathcal{H}_{i, 2}\right)$, together with a bundle morphism $\phi: \mathcal{H}_{i, 2} \rightarrow \mathcal{G}_{i, 2}$ such that $\mathcal{U}_{g, i}$ is the degeneracy locus of $\phi$.

Proof. Part (1) is an immediate consequence of (10), since we have the equivalence
$K_{i, 2}\left(C, K_{C} \otimes \eta\right)=0 \Leftrightarrow h^{0}\left(\mathbf{P}^{g-2}, \bigwedge^{i} M_{\mathbf{P}^{g}-2} \otimes \mathcal{I}_{C}(2)\right)=\binom{g-3}{i} \frac{(g-1)(g-2 i-6)}{i+2}$.
For part (2) one constructs two vector bundles $\mathcal{G}_{i, 2}$ and $\mathcal{H}_{i, 2}$ over $\mathbf{R}_{g}$ having fibres

$$
\mathcal{G}_{i, 2}[C, \eta]=H^{0}\left(C, \bigwedge^{i} M_{K_{C} \otimes \eta}(2)\right) \quad \text { and } \quad \mathcal{H}_{i, 2}[C, \eta]=H^{0}\left(\mathbf{P}^{g-2}, \bigwedge^{i} M_{\mathbf{P}^{g-2}}(2)\right) .
$$

There is a natural morphism $\phi: \mathcal{H}_{i, 2} \rightarrow \mathcal{G}_{i, 2}$ given by restriction. We have
$\operatorname{rank}\left(\mathcal{G}_{i, 2}\right)=\binom{g-2}{i}\left(-\frac{i(2 g-2)}{g-2}+3(g-1)\right) \quad$ and $\quad \operatorname{rank}\left(\mathcal{H}_{i, 2}\right)=(i+1)\binom{g}{i+2}$
and the condition that $\operatorname{rank}\left(\mathcal{G}_{i, 2}\right)=\operatorname{rank}\left(\mathcal{H}_{i, 2}\right)$ is equivalent to $g=2 i+6$.
We describe a set-up that will be used to define certain tautological sheaves over $\widetilde{\mathbf{R}}_{g}$ and compute the class $\left[\overline{\mathcal{U}}_{g, i}\right]^{\text {virt }}$. We use the notation from Subsection 1.1, in particular from Proposition 1.7 and recall that $f: \mathcal{X} \rightarrow \widetilde{\mathbf{R}}_{g}$ is the universal Prym curve, $\mathcal{P} \in$ $\operatorname{Pic}(\mathcal{X})$ denotes the universal Prym line bundle and $\mathcal{N}_{i}=f_{*}\left(\omega_{f}^{\otimes i} \otimes \mathcal{P}^{\otimes i}\right)$. We denote by $T:=\mathcal{E}_{0}^{\prime \prime} \cap \operatorname{Sing}(f)$ the codimension 2 subvariety corresponding to Wirtinger covers $\left[C_{y q}, \eta \in \operatorname{Pic}^{0}\left(C_{y q}\right)[2], \nu(y)=v(q)\right] \in \mathcal{X}$ (where $\nu^{*}(\eta)=\mathcal{O}_{C}$ ), with the marked point being the node of the underlying curve $C_{y q}$. Let us fix a point $\left[X:=C_{y q}, \eta, \beta\right] \in \widetilde{\Delta}_{0}^{\prime} \cup \widetilde{\Delta}_{0}^{\prime \prime}$ where as usual $v: C \rightarrow X$ is the normalization map. Then we have an identification

$$
\begin{equation*}
\mathcal{N}_{1}[X, \eta, \beta]=\operatorname{Ker}\left\{H^{0}\left(C, \omega_{C}(y+q) \otimes \eta_{C}\right) \rightarrow\left(v_{*} \mathcal{O}_{C} / \mathcal{O}_{X}\right) \otimes \omega_{X} \otimes \eta \cong \mathbb{C}_{y \sim q}\right\} \tag{11}
\end{equation*}
$$

where the map is given by taking the difference of residues at $y$ and $q$. Note that when $\eta_{C}=\mathcal{O}_{C}$, that is, when $[X, \eta, \beta] \in \widetilde{\Delta}_{0}^{\prime \prime}$, we have $\mathcal{N}_{1}[X, \eta, \beta]=H^{0}\left(C, \omega_{C}\right)$. For a point

$$
\left[X=C \cup_{\{y, q\}} E, \eta_{C} \in \sqrt{\mathcal{O}_{C}(-y-q)}, \eta_{E}\right] \in \widetilde{\Delta}_{0}^{\mathrm{ram}}
$$

we have an identification
$\mathcal{N}_{1}[X, \eta, \beta]=\operatorname{Ker}\left\{H^{0}\left(C, \omega_{C}(y+q) \otimes \eta_{C}\right) \oplus H^{0}\left(E, \mathcal{O}_{E}(1)\right) \rightarrow\left(\omega_{X} \otimes \eta\right)_{y, q} \cong \mathbb{C}_{y, q}^{2}\right\}$.
We set

$$
\begin{equation*}
\mathcal{M}:=\operatorname{Ker}\left\{f^{*}\left(\mathcal{N}_{1}\right) \rightarrow \omega_{f} \otimes \mathcal{P}\right\} . \tag{12}
\end{equation*}
$$

From the discussion above it is clear that the image of $f^{*}\left(\mathcal{N}_{1}\right) \rightarrow \omega_{f} \otimes \mathcal{P}$ is $\omega_{f} \otimes \mathcal{P} \otimes \mathcal{I}_{T}$. Since $T \subset \mathcal{X}$ is smooth of codimension 2 it follows that $\mathcal{M}$ is locally free. For $a, b \geq 0$, we define the sheaf $\mathcal{E}_{a, b}:=f_{*}\left(\bigwedge^{a} \mathcal{M} \otimes \omega_{f}^{\otimes b} \otimes \mathcal{P}^{\otimes b}\right)$ over $\widetilde{\mathbf{R}}_{g}$. Clearly $\mathcal{E}_{a, b}$ is locally free. We have $\mathcal{E}_{0, b}=\mathcal{N}_{b}$ for $b \geq 0$, and we always have left-exact sequences

$$
\begin{equation*}
0 \rightarrow \mathcal{E}_{a, b} \rightarrow \bigwedge^{a} \mathcal{E}_{0,1} \otimes \mathcal{E}_{0, b} \rightarrow \mathcal{E}_{a-1, b+1} \tag{13}
\end{equation*}
$$

which are right-exact off the divisor $\widetilde{\Delta}_{0}^{\prime \prime}$ (to be proved later). We then define inductively a sequence of vector bundles $\left\{\mathcal{H}_{a, b}\right\}_{a, b \geq 0}$ over $\widetilde{\mathbf{R}}_{g}$ in the following way: We set $\mathcal{H}_{0, b}:=$
$\operatorname{Sym}^{b}\left(\mathcal{N}_{1}\right)$ for each $b \geq 0$. Then having defined $\mathcal{H}_{a-1, b}$ for all $b \geq 0$, we define the vector bundle $\mathcal{H}_{a, b}$ by the exact sequence

$$
\begin{equation*}
0 \rightarrow \mathcal{H}_{a, b} \rightarrow \bigwedge^{a} \mathcal{H}_{0,1} \otimes \operatorname{Sym}^{b}\left(\mathcal{H}_{0,1}\right) \rightarrow \mathcal{H}_{a-1, b+1} \rightarrow 0 \tag{14}
\end{equation*}
$$

For a point $[X, \eta, \beta] \in \widetilde{\mathcal{R}}_{g}$, if we use the identification $H^{0}\left(X, \omega_{X} \otimes \eta\right)=$ $H^{0}\left(\mathbf{P}^{g-2}, \mathcal{O}_{\mathbf{P}^{g-2}}(1)\right)$, we have a natural identification of the fibre

$$
\mathcal{H}_{a, b}[X, \eta, \beta]=H^{0}\left(\mathbf{P}^{g-2}, \bigwedge^{a} M_{\mathbf{P}^{g-2}}(b)\right) .
$$

By induction on $a \geq 0$, there exist vector bundle morphisms $\phi_{a, b}: \mathcal{H}_{a, b} \rightarrow \mathcal{E}_{a, b}$.
Proposition 3.2. For $b \geq 2$ and $a \geq 0$ we have the vanishing of the higher direct images

$$
R^{1} f_{*}\left(\bigwedge^{a} \mathcal{M} \otimes \omega_{f}^{\otimes b} \otimes \mathcal{P}^{\otimes b}\right)_{\mid \mathbf{R}_{g} \cup \widetilde{\Delta}_{0}^{\prime} \cup \widetilde{\Delta}_{0}^{\mathrm{ram}}}=0
$$

It follows that the sequences 13 are right-exact off the divisor $\widetilde{\Delta}_{0}^{\prime \prime}$ of $\widetilde{\mathbf{R}}_{g}$.
Proof. Over the locus $\mathbf{R}_{g}$ the vanishing is a consequence of Proposition 2.4. For simplicity we prove that $R^{1} f_{*}\left(\bigwedge^{a} \mathcal{M} \otimes \omega_{f}^{\otimes b} \otimes \mathcal{P}^{\otimes b}\right) \otimes \mathcal{O}_{\widetilde{\Delta}_{0}^{\text {ram }}}=0$, the vanishing over $\widetilde{\Delta}_{0}^{\prime}$ being similar. We fix a point $\left[X=C \cup_{\{y, q\}} E, \eta_{C}, \eta_{E}\right] \in \widetilde{\Delta}_{0}^{\mathrm{ram}}$ with $\eta_{C}^{\otimes 2}=\mathcal{O}_{C}(-y-q), \eta_{E}=$ $\mathcal{O}_{E}(1)$ and set $L:=\omega_{X} \otimes \eta \in \operatorname{Pic}^{2 g-2}(X)$. We show that $H^{1}\left(X, \bigwedge^{a} M_{L} \otimes L^{\otimes b}\right)=0$ for all $a \geq 0$ and $b \geq 2$. A Mayer-Vietoris argument shows that it suffices to prove that

$$
\begin{gather*}
H^{1}\left(C, \bigwedge^{a} M_{L} \otimes L^{\otimes b} \otimes \mathcal{O}_{C}\right)=0, \quad H^{1}\left(E, \bigwedge^{a} M_{L} \otimes L^{\otimes b} \otimes \mathcal{O}_{E}\right)=0  \tag{15}\\
H^{1}\left(C, \bigwedge^{a} M_{L} \otimes L^{\otimes b} \otimes \mathcal{O}_{C}(-y-q)\right)=0 . \tag{16}
\end{gather*}
$$

For $L_{C}:=L \otimes \mathcal{O}_{C}=K_{C}(y+q) \otimes \eta_{C}$ and $L_{E}:=L_{E} \otimes \mathcal{O}_{E}$, we write the exact sequences

$$
\begin{aligned}
& 0 \rightarrow H^{0}\left(C, L_{C}(-y-q)\right) \otimes \mathcal{O}_{E} \rightarrow M_{L} \otimes \mathcal{O}_{E} \rightarrow M_{L_{E}} \rightarrow 0 \\
& 0 \rightarrow H^{0}\left(E, L_{E}(-y-q)\right) \otimes \mathcal{O}_{C} \rightarrow M_{L} \otimes \mathcal{O}_{C} \rightarrow M_{L_{C}} \rightarrow 0
\end{aligned}
$$

and we find that $M_{L} \otimes \mathcal{O}_{C}=M_{L_{C}}$ while obviously $M_{L_{E}}=\mathcal{O}_{E}(-1)$. We conclude that the statements (15) and for all $a \geq 0$ and $b \geq 2$ can be reduced to showing that

$$
\begin{aligned}
& H^{1}\left(C, \bigwedge^{a} M_{L_{C}} \otimes L_{C}^{\otimes b}\right) \\
& \quad=H^{1}\left(C, \bigwedge^{a} M_{L_{C}} \otimes L_{C}^{\otimes b} \otimes \mathcal{O}_{C}(-y-q)\right)=0 \quad \text { for all } a \geq 0, b \geq 2
\end{aligned}
$$

This is now a direct application of Proposition 2.4
Proof of Theorem 0.6. We have constructed the vector bundle morphism $\phi_{i, 2}: \mathcal{H}_{i, 2} \rightarrow$ $\mathcal{E}_{i, 2}$ over $\widetilde{\mathbf{R}}_{g}$. For $g=2 i+6$ we have $\operatorname{rank}\left(\mathcal{H}_{i, 2}\right)=\operatorname{rank}\left(\mathcal{E}_{i, 2}\right)$ and the virtual Koszul class $\left[\overline{\mathcal{U}}_{g, i}\right]^{\text {virt }}$ is given by $c_{1}\left(\mathcal{E}_{i, 2}-\mathcal{H}_{i, 2}\right)$. We recall that for a rank $e$ vector bundle $\mathcal{E}$ over a
variety $X$ and for $i \geq 1$, we have the formulas $c_{1}\left(\bigwedge^{i} \mathcal{E}\right)=\binom{e-1}{i-1} c_{1}(\mathcal{E})$ and $c_{1}\left(\operatorname{Sym}^{i}(\mathcal{E})\right)=$ $\binom{e+i-1}{e} c_{1}(\mathcal{E})$. Using 13 we find that there exists a constant $\alpha \geq 0$ such that

$$
\begin{aligned}
c_{1}\left(\mathcal{E}_{i, 2}\right)-\alpha \cdot \delta_{0}^{\prime \prime}= & \sum_{l=0}^{i}(-1)^{l} c_{1}\left(\bigwedge^{i-l} \mathcal{E}_{0,1} \otimes \mathcal{E}_{0, l+2}\right)=\sum_{l=0}^{i}(-1)^{l}\binom{g-1}{i-l} c_{1}\left(\mathcal{E}_{0, l+2}\right) \\
& +\sum_{l=0}^{i}(-1)^{l}((g-1)(2 l+3))\binom{g-2}{i-l-1} c_{1}\left(\mathcal{E}_{0,1}\right)
\end{aligned}
$$

while a repeated application of the exact sequence (14) gives that

$$
\begin{aligned}
c_{1}\left(\mathcal{H}_{i, 2}\right) & =\sum_{l=0}^{i}(-1)^{l} c_{1}\left(\bigwedge^{i-l} \mathcal{H}_{0,1} \otimes \operatorname{Sym}^{l+2}\left(\mathcal{H}_{0,1}\right)\right) \\
& =\sum_{l=0}^{i}(-1)^{l}\left(\binom{g-1}{i-l} c_{1}\left(\operatorname{Sym}^{l+2}\left(\mathcal{H}_{0,1}\right)\right)+\binom{g+l}{l+2} c_{1}\left(\bigwedge^{i-l} \mathcal{H}_{0,1}\right)\right) \\
& =\sum_{l=0}^{i}(-1)^{l}\left(\binom{g-1}{i-l}\binom{g+l}{g-1}+\binom{g+l}{l+2}\binom{g-2}{i-l-1}\right) c_{1}\left(\mathcal{H}_{0,1}\right)
\end{aligned}
$$

with $\mathcal{E}_{0,1}=\mathcal{H}_{0,1}=\mathcal{N}_{1}$ and $\mathcal{E}_{0, l+2}=\mathcal{N}_{l+2}$ for $l \geq 0$. Proposition 1.7 finishes the proof.

Comparing these formulas with the canonical class of $\overline{\mathcal{R}}_{g}$, one finds that $\overline{\mathcal{R}}_{g}$ is of general type for $g>12$.

## 4. Effective divisors on $\overline{\mathcal{R}}_{g}$

We now use in an essential way results from [F3] to produce myriads of effective divisors on $\overline{\mathcal{R}}_{g}$. This construction, though less explicit than that of $\overline{\mathcal{U}}_{2 i+6}$ and $\overline{\mathcal{D}}_{g: k}$, is still very effective and we use it to show $\overline{\mathcal{R}}_{18}, \overline{\mathcal{R}}_{20}$ and $\overline{\mathcal{R}}_{22}$ are of general type.

We consider the morphism $\chi: \overline{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{M}}_{2 g-1}$ given by $\chi([C, \eta]):=[\tilde{C}]$, where $f: \tilde{C} \rightarrow C$ is the étale double cover determined by $\eta$. Thus one has

$$
\begin{aligned}
f_{*} \mathcal{O}_{\tilde{C}} & =\mathcal{O}_{C} \oplus \eta \text { and } \\
H^{i}\left(\tilde{C}, f^{*} L\right) & =H^{i}(C, L) \oplus H^{i}(C, L \otimes \eta) \quad \text { for any } L \in \operatorname{Pic}(C), i=0,1
\end{aligned}
$$

The pullback map $\chi^{*}$ at the level of Picard groups has been determined by M. Bernstein in [Be, Lemma 3.1.3]. We record her results:
Proposition 4.1. The pullback map $\chi^{*}: \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right) \rightarrow \operatorname{Pic}\left(\overline{\mathcal{M}}_{2 g-1}\right)$ is given as follows:

$$
\begin{aligned}
\chi^{*}(\lambda)=2 \lambda-\frac{1}{4} \delta_{0}^{\mathrm{ram}}, \quad \chi^{*}\left(\delta_{0}\right)=\delta_{0}^{\mathrm{ram}}+2\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}+\sum_{i=1}^{[g / 2]} \delta_{i: g-i}\right), \\
\chi^{*}\left(\delta_{i}\right)=2 \delta_{g-i} \quad \text { for } 1 \leq i \leq g-1 .
\end{aligned}
$$

Proof. The formula for $\chi^{*}\left(\delta_{i}\right)$ when $1 \leq i \leq g-1$ is immediate. To determine $\chi^{*}(\lambda)$ one notices that $\chi^{*}\left(\left(\kappa_{1}\right)_{\overline{\mathcal{M}}_{2 g-1}}\right)=2\left(\kappa_{1}\right)_{\overline{\mathcal{R}}_{g}}$ and the rest follows from Mumford's formulas $\left(\kappa_{1}\right) \overline{\mathcal{M}}_{2 g-1}=12 \lambda-\delta \in \operatorname{Pic}\left(\overline{\mathcal{M}}_{2 g-1}\right)$ and $\left(\kappa_{1}\right)_{\overline{\mathcal{R}}_{g}}=12 \lambda-\pi^{*}(\delta) \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{g}\right)$.
We set the integer $g^{\prime}:=1+\frac{g-1}{g}\binom{2 g}{g-1}$. In [F3] we have studied the rational map

$$
\phi: \overline{\mathcal{M}}_{2 g-1} \rightarrow \overline{\mathcal{M}}_{1+\frac{g-1}{g}\left({ }_{g-1}^{2 g}\right)}, \quad \phi[Y]:=W_{g+1}^{1}(Y),
$$

and determined the pullback map at the level of divisors $\phi^{*}: \operatorname{Pic}\left(\overline{\mathcal{M}}_{g^{\prime}}\right) \rightarrow \operatorname{Pic}\left(\overline{\mathcal{M}}_{2 g-1}\right)$. In particular, we proved that if $A \in \operatorname{Pic}\left(\overline{\mathcal{M}}_{g^{\prime}}\right)$ is a divisor of slope $s(A)=s$, then the slope of the pullback $\phi^{*}(A)$ is equal to (cf. [F3, Theorem 0.2])

$$
\begin{equation*}
s\left(\phi^{*}(A)\right)=6+\frac{8 g^{3} s-32 g^{3}-19 g^{2} s+66 g^{2}+6 g s-16 g+3 s+6}{(g-1)(g+1)\left(g^{2} s-2 g s-4 g^{2}+7 g+3\right)} . \tag{17}
\end{equation*}
$$

To obtain effective divisors of small slope on $\overline{\mathcal{R}}_{g}$ we shall consider pullbacks $(\phi \chi)^{*}(A)$, where $A \in \operatorname{Ample}\left(\overline{\mathcal{M}}_{g^{\prime}}\right)$. (Of course, one can consider the cone $\chi^{*}\left(\operatorname{Ample}\left(\overline{\mathcal{M}}_{2 g-1}\right)\right.$ ), but a quick look at Proposition 4.1 shows that it is impossible to obtain in this way divisors on $\overline{\mathcal{R}}_{g}$ satisfying the inequalities 2 . Pulling back merely effective divisors $\overline{\mathcal{M}}_{2 g-1}$, rather than ample ones, is problematic since $\chi\left(\overline{\mathcal{R}}_{g}\right)$ tends to be contained in many geometric divisors on $\overline{\mathcal{M}}_{2 g-1}$.) In order for the pullbacks $\chi^{*} \phi^{*}(A)$ to be well-defined as effective divisors on $\overline{\mathcal{R}}_{g}$ we prove the following result:

Proposition 4.2. If $\operatorname{dom}(\phi) \subset \overline{\mathcal{M}}_{2 g-1}$ is the domain of definition of the rational morphism $\phi: \overline{\mathcal{M}}_{2 g-1} \rightarrow \overline{\mathcal{M}}_{g^{\prime}}$, then $\chi\left(\overline{\mathcal{R}}_{g}\right) \cap \operatorname{dom}(\phi) \neq \emptyset$. It follows that for any ample divisor $A \in \operatorname{Ample}\left(\overline{\mathcal{M}}_{g^{\prime}}\right)$, the pullback $\chi^{*} \phi^{*}(A) \in \operatorname{Eff}\left(\overline{\mathcal{R}}_{g}\right)$ is well-defined.
Proof. We take a general point $\left[C \cup_{y} E, \eta_{C}=\mathcal{O}_{C}, \eta_{E}\right] \in \Delta_{1} \subset \overline{\mathcal{R}}_{g}$. The corresponding admissible double cover is then $f: C_{1} \cup_{y_{1}} \widetilde{E} \cup_{y_{2}} C_{2} \rightarrow C \cup_{y} E$, where $\left[C_{1}, y_{1}\right]$ and [ $C_{2}, y_{2}$ ] are copies of $[C, y]$ mapping isomorphically to $[C, y]$, and $f: \widetilde{E} \rightarrow E$ is the étale double cover induced by the torsion point $\eta_{E} \in \operatorname{Pic}^{0}(E)[2]$. We have $C_{i} \cap \widetilde{E}=\left\{y_{i}\right\}$, where $f_{\widetilde{E}}\left(y_{1}\right)=f_{\widetilde{E}}\left(y_{2}\right)=y$. Thus $\chi\left[C \cup E, \mathcal{O}_{C}, \eta_{E}\right]:=\left[C_{1} \cup_{y_{1}} \widetilde{E} \cup_{y_{2}} C_{2}\right]$, where $y_{1}, y_{2} \in \widetilde{E}$ are such that $\mathcal{O}_{\widetilde{E}}\left(y_{1}-y_{2}\right)$ is a 2 -torsion point in $\operatorname{Pic}^{0}(\widetilde{E})$.

Suppose now that $X:=C_{1} \cup_{y_{1}} E \cup_{y_{2}} C_{2}$ is a curve of compact type such that $\left[C_{i}, y_{i}\right] \in \mathcal{M}_{g-1,1}(i=1,2)$ and $\left[E, y_{1}, y_{2}\right] \in \mathcal{M}_{1,2}$ are all Brill-Noether general. In particular, the class $y_{1}-y_{2} \in \operatorname{Pic}^{0}(E)$ is not torsion. Then $\phi([X]):=\left[\bar{W}_{g+1}^{1}(X)\right]$ is the variety of limit linear series $\mathfrak{g}_{g+1}^{1}$ on $X$. The general point of each irreducible component of $\bar{W}_{g+1}^{1}(X)$ corresponds to a refined linear series $l$ on $X$ satisfying the following compatibility conditions in terms of Brill-Noether numbers (see also [EH], [F3]):

$$
\begin{align*}
& 1=\rho\left(l_{C_{1}}, y_{1}\right)+\rho\left(l_{C_{2}}, y_{2}\right)+\rho\left(l_{E}, y_{1}, y_{2}\right)=1, \\
& \rho\left(l_{C_{1}}, y_{1}\right), \rho\left(l_{C_{2}}, y_{2}\right), \rho\left(l_{E}, y_{1}, y_{2}\right) \geq 0 . \tag{18}
\end{align*}
$$

If $\rho\left(l_{C_{2}}, y_{2}\right)=1$, we find two types of components of $\bar{W}_{g+1}^{1}(X)$ which we describe: Since $\rho\left(l_{C_{1}}, y_{1}\right)=0$, there exists an integer $0 \leq a \leq g / 2$ such that $a^{l_{C_{1}}}\left(y_{1}\right)=(a, g+2-a)$.

On $E$ there are two choices for $l_{E} \in G_{g+1}^{1}(E)$ such that $a^{l_{E}}\left(y_{1}\right)=(a-1, g+1-a)$. Either $a^{l_{E}}\left(y_{2}\right)=(a, g+1-a)$ (there is a unique such $\left.l_{E}\right)$, and then $l_{C_{2}}$ belongs to the connected curve $T_{a}:=\left\{l_{C_{2}} \in G_{g+1}^{1}\left(C_{2}\right): a^{l_{C_{2}}}\left(y_{2}\right) \geq(a, g+1-a)\right\}$, or else, $a^{l_{E}}\left(y_{2}\right)=(a-1, g+2-a)$ (again, there is a unique such $l_{E}$ ), and then the $C_{2}$-aspect of $l$ belongs to the curve $T_{a}^{\prime}:=\left\{l_{C_{2}} \in G_{g+1}^{1}\left(C_{2}\right): a^{l_{C_{2}}}\left(y_{2}\right) \geq(a-1, g+2-a)\right\}$. Thus $\left\{l_{C_{1}}\right\} \times T_{a}$ and $\left\{l_{C_{2}}\right\} \times T_{a}^{\prime}$ are irreducible components of $\bar{W}_{g+1}^{1}(X)$. If $\rho\left(l_{E}, y_{1}, y_{2}\right)=1$, then there are three types of irreducible components of $\bar{W}_{g+1}^{1}(X)$ corresponding to the cases

$$
\begin{array}{lll}
a^{l_{E}}\left(y_{1}\right)=(a-1, g+1-a), & a^{l_{E}}\left(y_{2}\right)=(a-1, g+1-a) & \text { for } 0 \leq a \leq g / 2, \\
a^{l_{E}}\left(y_{1}\right)=(a-1, g+1-a), & a^{l_{E}}\left(y_{2}\right)=(a, g-a) & \text { for } 1 \leq a \leq(g-1) / 2, \\
a^{l_{E}}\left(y_{1}\right)=(a-1, g+1-a), & a^{l_{E}}\left(y_{2}\right)=(a-2, g+2-a) & \text { for } 2 \leq a \leq(g-1) / 2 .
\end{array}
$$

Finally, the case $\rho\left(l_{C_{1}}, y_{1}\right)=1$ is identical to the case $\rho\left(l_{C_{2}}, y_{2}\right)=1$ by reversing the roles of the curves $C_{1}$ and $C_{2}$. The singular points of $\bar{W}_{g+1}^{1}(X)$ correspond to (necessarily) crude limit $\mathfrak{g}_{g+1}^{1}$ 's satisfying $\rho\left(l_{C_{1}}, y_{1}\right)=\rho\left(l_{C_{2}}, y_{2}\right)=\rho\left(l_{E}, y_{1}, y_{2}\right)=0$. For such $l$, there must exist two irreducible components of $X$, say $Y$ and $Z$, for which $Y \cap Z=\{x\}$ and such that $a_{0}^{l_{Y}}(x)+a_{1}^{l_{Z}}(x)=g+2$ and $a_{1}^{l_{Y}}(x)+a_{0}^{l_{Z}}(x)=g+1$. The point $l$ lies precisely on the two irreducible components of $\bar{W}_{g+1}^{1}(X)$ : The one corresponding to refined limit $\mathfrak{g}_{g+1}^{1}$ with vanishing sequence on $Y$ equal to $\left(a_{0}^{l_{Y}}(x)-1, a_{1}^{l_{Y}}(x)\right)$, and the one with vanishing $\left(a_{0}^{l_{Z}}(x), a_{1}^{l_{Z}}(x)-1\right)$ on $Z$. Thus $\bar{W}_{g+1}^{1}(X)$ is a stable curve of compact type, so $[X] \in \operatorname{dom}(\phi)$. Using [F3], this set-theoretic description applies to the image under $\phi$ of any point $\left[C_{1} \cup_{y_{1}} E \cup_{y_{2}} C_{2}\right]$, in particular to [ $\left.C_{1} \cup_{y_{1}} \widetilde{E} \cup_{y_{2}} C_{2}\right]=\chi\left(\left[C \cup_{y} E\right]\right)$. We have shown that $\chi\left(\Delta_{1}\right) \cap \operatorname{dom}(\phi) \neq \emptyset$.
Proof of Theorem 0.1 for genus $g=18,20,22$. We construct an effective divisor on $\overline{\mathcal{R}}_{g}$ which satisfies the inequalities (2) and which is of the form
$\mu \pi^{*}(D)+\epsilon \chi^{*} \phi^{*}(A)=\alpha \lambda-2\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-3 \delta_{0}^{\mathrm{ram}}-\sum_{i=1}^{[g / 2]}\left(b_{i} \delta_{i}+b_{g-i} \delta_{g-i}+b_{i: g-i} \delta_{i: g-i}\right)$,
where $A \equiv s \lambda-\delta \in \operatorname{Pic}\left(\overline{\mathcal{M}}_{g^{\prime}}\right)$ is an ample class (which happens precisely when $s>11$, cf. $[\overline{\mathrm{CH}}]), D \in \operatorname{Eff}\left(\overline{\mathcal{M}}_{g}\right)$ and $\mu, \epsilon>0$ and $\alpha<13$. We solve this linear system using Proposition 4.1 and find that we must have

$$
\epsilon=\frac{8}{12-s\left(\phi^{*}(A)\right)} \quad \text { and } \quad \mu=\frac{16-2 s\left(\phi^{*}(A)\right)}{12-s\left(\phi^{*}(A)\right)}
$$

To conclude that $\overline{\mathcal{R}}_{g}$ is of general type, it suffices to check that the inequality

$$
\alpha=\frac{8 s\left(\phi^{*}(A)\right)}{12-s\left(\phi^{*}(A)\right)}+\left(6+\frac{12}{g+1}\right) \frac{16-2 s\left(\phi^{*}(A)\right)}{12-s\left(\phi^{*}(A)\right)}<13
$$

has a solution $s=s(A) \geq 11$. Using (17), we find that this is the case for $g \geq 18$.

## 5. The enumerative geometry of $\overline{\mathcal{R}}_{g}$ in small genus

In this section we describe the divisors $\mathcal{D}_{g: k}$ and $\mathcal{U}_{g, i}$ for small $g$. We start with the case $g=3$. This result has been first obtained by M. Bernstein [Be, Theorem 3.2.3] using test curves inside $\overline{\mathcal{R}}_{3}$. Our method is more direct and uses the identification of cycles $C-C=\Theta_{Q_{C}} \subset \operatorname{Pic}^{0}(C)$, valid for all curves $[C] \in \mathcal{M}_{3}$.

Theorem 5.1. The divisor $\mathcal{D}_{3: 2}=\left\{[C, \eta] \in \mathcal{R}_{3}: \eta \in C-C\right\}$ is equal to the locus of étale double covers $[\tilde{C} \xrightarrow{f} C] \in \mathcal{R}_{3}$ such that $[\tilde{C}] \in \mathcal{M}_{5}$ is hyperelliptic. We have the equality of cycles $\overline{\mathcal{D}}_{3: 2} \equiv 8 \lambda-\delta_{0}^{\prime}-2 \delta_{0}^{\prime \prime}-\frac{3}{2} \delta_{0}^{\mathrm{ram}}-6 \delta_{1}-4 \delta_{2}-2 \delta_{1: 2} \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{3}\right)$. Moreover,

$$
\pi_{*}\left(\overline{\mathcal{D}}_{3: 2}\right) \equiv 56 \cdot \overline{\mathcal{M}}_{3,2}^{1}=56 \cdot\left(9 \lambda-\delta_{0}-3 \delta_{1}\right) \in \operatorname{Pic}\left(\overline{\mathcal{M}}_{3}\right) .
$$

This equality corresponds to the fact that for an étale double cover $f: \tilde{C} \rightarrow C$, the source $\tilde{C}$ is hyperelliptic if and only if $C$ is hyperelliptic and $\eta \in C-C \subset \operatorname{Pic}^{0}(C)$.
Proof. We use the set-up from Theorem 2.8 and recall that there exists a vector bundle morphism $\phi: \mathcal{H} \otimes \mathcal{A}_{0,0} \rightarrow \mathcal{A}_{0,1}$ over $\overline{\mathbf{R}}_{3}^{0}$ such that $Z_{1}(\phi) \cap \mathcal{R}_{3}=\mathcal{D}_{3: 2}$. Here $\mathcal{H}=$ $\pi^{*}(\mathbb{E}), \mathcal{A}_{0,0}[X, \eta, \beta]={\underset{\sim}{R}}^{0}\left(X, \omega_{X} \otimes \beta\right)$ and $\mathcal{A}_{0,1}[X, \eta, \beta]=H^{0}\left(X, \omega_{X}^{\otimes 2} \otimes \beta\right)$, for each point $[X, \eta, \beta] \in \widetilde{\mathcal{R}}_{g}$. Using $\sqrt[11]{ }$ and 12$]$ we check that both $\phi_{\mid \Delta_{0}^{\prime}}$ and $\phi_{\mid \Delta_{0}^{\text {ram }}}$ are generically non-degenerate. Over a point $t=\left[C_{y q}, \eta, \beta\right] \in \Delta_{0}^{\prime \prime}$ corresponding to a Wirtinger covering (i.e. $v: C \rightarrow C_{y q}$ with $[C] \in \mathcal{M}_{2}$ and $v^{*}(\eta)=\mathcal{O}_{C}$ ), we have
$\phi(t): H^{0}\left(C, K_{C}\right) \otimes H^{0}\left(C, K_{C} \otimes \mathcal{O}_{C}(y+q)\right) \rightarrow \mathcal{A}_{0,1}(t) \subset H^{0}\left(C, \omega_{C}^{\otimes 2} \otimes \mathcal{O}_{C}(2 y+2 q)\right)$.
From the base point free pencil trick we find that $\operatorname{Ker}(\phi(t))=H^{0}\left(C, \mathcal{O}_{C}(y+q)\right)$, that is, $\phi_{\mid \Delta_{0}^{\prime \prime}}$ is everywhere degenerate and the class $c_{1}\left(\mathcal{A}_{0,1}-\mathcal{H} \otimes \mathcal{A}_{0,0}\right)-\delta_{0}^{\prime \prime} \in \operatorname{Pic}\left(\overline{\mathbf{R}}_{3}^{0}\right)$ is effective. From the formulas $\pi_{*}(\lambda)=63 \lambda, \pi_{*}\left(\delta_{0}^{\prime}\right)=30 \delta_{0}, \pi_{*}\left(\delta_{0}^{\prime \prime}\right)=\delta_{0}$ and $\pi_{*}\left(\delta_{0}^{\mathrm{ram}}\right)=$ $16 \delta_{0}$, we obtain

$$
s\left(\pi_{*}\left(c_{1}\left(\mathcal{A}_{0,1}-\mathcal{H} \otimes \mathcal{A}_{0,0}\right)-\delta_{0}^{\prime \prime}\right)\right)=9 .
$$

The hyperelliptic locus $\overline{\mathcal{M}}_{3,2}^{1}$ is the only divisor on $D \in \operatorname{Eff}\left(\overline{\mathcal{M}}_{3}\right)$ with $\Delta_{i} \varsubsetneqq \operatorname{supp}(D)$ for $i=0,1$ and $s(D) \leq 9$, which leads to the formula $\pi_{*}\left(\overline{\mathcal{D}}_{3: 2}\right)=56 \cdot \overline{\mathcal{M}}_{3,2}^{1}$.

Theorem 5.2. The divisor $\overline{\mathcal{D}}_{5: 2}:=\left\{[C, \eta] \in \mathcal{R}_{5}: \eta \in C_{2}-C_{2}\right\}$ equals the locus of étale double covers $[\tilde{C} \xrightarrow{f} C] \in \mathcal{R}_{5}$ such that the genus 9 curve $\tilde{C}$ is tetragonal. We have the formula $\overline{\mathcal{D}}_{5: 2}=14 \lambda-2\left(\delta_{0}^{\prime}+\delta_{0}^{\prime \prime}\right)-\frac{5}{2} \delta_{0}^{\text {ram }}-10 \delta_{4}-4 \delta_{1: 4}-\cdots \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{5}\right)$.

Proof. We start with an étale cover $f: \tilde{C} \xrightarrow{2: 1} C$ corresponding to the torsion point $\eta=\mathcal{O}_{C}(D-E)$ with $D, E \in C_{2}$. Then

$$
H^{0}\left(\tilde{C}, \mathcal{O}_{\tilde{C}}\left(f^{*} D\right)\right)=H^{0}\left(C, \mathcal{O}_{C}(D)\right) \oplus H^{0}\left(C, \mathcal{O}_{C}(E)\right)
$$

that is, $\left|f^{*} D\right| \in G_{4}^{1}(\tilde{C})$ and $[\tilde{C}] \in \overline{\mathcal{M}}_{9,4}^{1}$. Conversely, if $l \in G_{4}^{1}(\tilde{C})$, then $l$ must be invariant under the involution of $\tilde{C}$ and then $f_{*}(l) \in G_{4}^{1}(C)$ contains two divisors of the type $2 x+2 y \equiv 2 p+2 q$. Then we take $\eta=\mathcal{O}_{C}(x+y-p-q)$, that is, $[C, \eta] \in \mathcal{D}_{5: 2}$.

Remark 5.3. Since $\operatorname{codim}\left(\overline{\mathcal{M}}_{9,4}^{1}, \overline{\mathcal{M}}_{9}\right)=3$ while $\mathcal{D}_{5: 2}$ is a divisor in $\mathcal{R}_{3}$, there seems to be a dimensional discrepancy in Theorem 5.2 This is explained by noting that for an étale double covering $f: \tilde{C} \rightarrow C$ over a general curve $[C] \in \mathcal{M}_{5}$, the codimension 1 condition $\operatorname{gon}(\tilde{C}) \leqq 5$ is equivalent to the seemingly stronger condition gon $(\tilde{C}) \leq 4$. Indeed, if $l \in G_{5}^{1}(\tilde{C})$ is base point free, then $l$ is not invariant under the involution of $\tilde{C}$ and $\operatorname{dim}\left|f_{*} l\right| \geq 2$ so $G_{5}^{2}(C) \neq \emptyset$, a contradiction with the genericity assumption on $C$.

Theorem 5.4. The divisor $\mathcal{D}_{4: 3}=\left\{[C, \eta] \in \mathcal{R}_{4}: \exists A \in W_{3}^{1}(C)\right.$ with $\left.H^{0}(C, A \otimes \eta) \neq 0\right\}$ can be identified with the locus of Prym curves $[C, \eta] \in \mathcal{R}_{4}$ such that the Prym-canonical model $C \xrightarrow{\left|K_{C} \otimes \eta\right|} \mathbf{P}^{2}$ is a plane sextic curve with a triple point. We also have the class formula

$$
\overline{\mathcal{D}}_{4: 3} \equiv 8 \lambda-\delta_{0}^{\prime}-2 \delta_{0}^{\prime \prime}-\frac{7}{4} \delta_{0}^{\mathrm{ram}}-4 \delta_{3}-7 \delta_{1}-3 \delta_{1: 3}-\cdots \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{4}\right)
$$

hence $\pi_{*}\left(\overline{\mathcal{D}}_{4: 3}\right)=60 \cdot \overline{\mathcal{G P}}_{4,3}^{1}=60\left(34 \lambda-4 \delta_{0}-14 \delta_{1}-18 \delta_{2}\right) \in \operatorname{Pic}\left(\overline{\mathcal{M}}_{4}\right)$, where

$$
\left.\mathcal{G} \mathcal{P}_{4,3}^{1} \subset \mathcal{M}_{4}:=\{C] \in \mathcal{M}_{4}: \exists A \in W_{3}^{1}(C), A^{\otimes 2}=K_{C}\right\}
$$

is the Gieseker-Petri divisor of curves $[C] \in \mathcal{M}_{4}$ with a vanishing theta-null.
Proof. We start with a Prym curve $[C, \eta] \in \mathcal{R}_{4}$ such that there exists $A \in W_{3}^{1}(C)$ with $H^{0}(C, A \otimes \eta) \neq 0$. We claim that $A^{\otimes 2}=K_{C}$, that is, $[C] \in \mathcal{G} \mathcal{P}_{4,3}^{1}$. Indeed, assuming the opposite, we find disjoint divisors $D_{1}, D_{2} \in C_{3}$ such that $D_{1} \in|A \otimes \eta|$ and $D_{2} \in$ $\left|K_{C} \otimes A^{\vee} \otimes \eta\right|$. In particular, the subspaces $H^{0}\left(C, K_{C} \otimes \eta\left(-D_{i}\right)\right) \subset H^{0}\left(C, K_{C}\right)$ are both of dimension 2 , hence they intersect non-trivially, that is, $H^{0}\left(C, K_{C} \otimes \eta\left(-D_{1}-D_{2}\right)\right) \neq 0$. Since $D_{1}+D_{2} \equiv K_{C}$, this implies $\eta=0$, a contradiction.

The proof that the vector bundle morphism $\phi: \mathcal{H} \otimes \mathcal{A}_{0,0} \rightarrow \mathcal{A}_{0,1}$ constructed in the proof of Theorem 2.8 is degenerate with order 1 along the divisor $\Delta_{0}^{\prime \prime} \subset \overline{\mathcal{R}}_{4}$ follows from 11). Thus $c_{1}\left(\mathcal{A}_{0,1}-\mathcal{H} \otimes \mathcal{A}_{0,0}\right)-\delta_{0}^{\prime \prime} \in \operatorname{Pic}\left(\overline{\mathcal{R}}_{4}\right)$ is an effective class and its pushforward to $\overline{\mathcal{M}}_{4}$ has slope $17 / 2$. The only divisor $D \in \operatorname{Eff}\left(\overline{\mathcal{M}}_{4}\right)$ with $\Delta_{i} \varsubsetneqq \operatorname{supp}(D)$ for $i=0,1,2$ and $s(D) \leq 17 / 2$ is the theta-null divisor $\overline{\mathcal{G P}}_{4,3}^{1}$ (cf. [F3], Theorem 5.1]).

Remark 5.5. For a general point $[C, \eta] \in \mathcal{R}_{4}$, the Prym-canonical curve $\iota: C \xrightarrow{\left|K_{C} \otimes \eta\right|} \mathbf{P}^{2}$ is a plane sextic with 6 nodes which correspond to the preimages in $\phi^{-1}(\eta)$ under the second difference map

$$
C_{2} \times C_{2} \rightarrow \operatorname{Pic}^{0}(C), \quad\left(D_{1}, D_{2}\right) \mapsto \mathcal{O}_{C}\left(D_{1}-D_{2}\right) .
$$

Note that $W_{2}(C) \cdot\left(W_{2}(C)+\eta\right)=6$. For a general $[C, \eta] \in \mathcal{D}_{4: 3}$, the model $\iota(C) \subset \mathbf{P}^{2}$ has a triple point. For a hyperelliptic curve $[C] \in \mathcal{M}_{4,2}^{1}$, out of the $255=2^{2 g}-1$ étale double covers of $C$, there exist 210 for which $C \xrightarrow{\left|K_{C} \otimes \eta\right|} \mathbf{P}^{2}$ has an ordinary 4-fold point and no other singularity. The remaining $45=\binom{2 g+2}{2}$ coverings correspond to the case $\eta=\mathcal{O}_{C}(x-y)$, with $x, y \in C$ being Weierstrass points, when $\left|K_{C} \otimes \eta\right|$ has two base points and $\iota$ is a degree 2 map onto a conic.

## 6. The singularities of the moduli space of Prym curves

The moduli space $\overline{\mathcal{R}}_{g}$ is a normal variety with finite quotient singularities. To determine its Kodaira dimension we consider a smooth model $\widehat{\mathcal{R}}_{g}$ of $\overline{\mathcal{R}}_{g}$ and then analyze the growth of the dimension of the spaces $H^{0}\left(\widehat{\mathcal{R}}_{g}, K_{\widehat{\mathcal{R}}_{g}}^{\otimes l}\right)$ of pluricanonical forms for all $l \geq 0$. In this section we show that in doing so one only needs to consider forms defined on $\overline{\mathcal{R}}_{g}$ itself.
Theorem 6.1. Fix $g \geq 4$ and let $\widehat{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{R}}_{g}$ be any desingularization. Then every pluricanonical form defined on the smooth locus $\overline{\mathcal{R}}_{g}^{\text {reg }}$ of $\overline{\mathcal{R}}_{g}$ extends holomorphically to $\widehat{\mathcal{R}}_{g}$, that is, for all integers $l \geq 0$ we have isomorphisms

$$
H^{0}\left(\overline{\mathcal{R}}_{g}^{\mathrm{reg}}, K_{\overline{\mathcal{R}}_{g}}^{\otimes l}\right) \cong H^{0}\left(\widehat{\mathcal{R}}_{g}, K_{\widehat{\mathcal{R}}_{g}}^{\otimes l}\right)
$$

A similar statement has been proved for the moduli space $\overline{\mathcal{M}}_{g}$ of curves (cf. [HM, Theorem 1]) and for the moduli space $\overline{\mathcal{S}}_{g}$ of spin curves (cf. [Lud, Theorem 4.1]). We start by explicitly describing the locus of non-canonical singularities in $\overline{\mathcal{R}}_{g}$, which has codimension 2. At a non-canonical singularity there exist local pluricanonical forms that do acquire poles on a desingularization. We show that this situation does not occur for forms defined on the smooth locus $\overline{\mathcal{R}}_{g}^{\text {reg }}$, and they extend holomorphically to $\widehat{\mathcal{R}}_{g}$.

Definition 6.2. An automorphism of a Prym curve $(X, \eta, \beta)$ is an automorphism $\sigma \in$ $\operatorname{Aut}(X)$ such that there exists an isomorphism of sheaves $\gamma: \sigma^{*} \eta \rightarrow \eta$ making the following diagram commutative:

If $C:=\operatorname{st}(X)$ denotes the stable model of $X$ then there is a group homomorphism $\operatorname{Aut}(X, \eta, \beta) \rightarrow \operatorname{Aut}(C)$ given by $\sigma \mapsto \sigma_{C}$. The kernel $\operatorname{Aut}_{0}(X, \eta, \beta)$ of this homomorphism is called the subgroup of inessential automorphisms of $(X, \eta, \beta)$.
Remark 6.3. The subgroup $\operatorname{Aut}_{0}(X, \eta, \beta)$ is isomorphic to $\{ \pm 1\}^{C C(\widetilde{X})} / \pm 1$, where $C C(\widetilde{X})$ is the set of connected components of the non-exceptional subcurve $\widetilde{X}$ (compare [CCC, Lemma 2.3.2] and [Lud, Proposition 2.7]). Given $\gamma_{j} \in\{ \pm 1\}$ for every connected component $\widetilde{X}_{j}$ of $\widetilde{X}$ consider the automorphism $\tilde{\gamma}$ of $\widetilde{\eta}=\eta_{\mid} \tilde{X}$ which is multiplication by $\gamma_{j}$ in every fibre over $\tilde{X}_{j}$. Then there exists a unique inessential automorphism $\sigma$ such that $\widetilde{\gamma}$ extends to an isomorphism $\gamma: \sigma^{*} \eta \rightarrow \eta$ compatible with the morphisms $\sigma^{*} \beta$ and $\beta$. Considering $\left(-\gamma_{j}\right)_{j}$ instead of $\left(\gamma_{j}\right)_{j}$ gives the same automorphism $\sigma$.

Definition 6.4. For a quasi-stable curve $X$, an irreducible component $C_{j}$ is called an elliptic tail if $p_{a}\left(C_{j}\right)=1$ and $C_{j} \cap \overline{\left(X-C_{j}\right)}=\{p\}$. The node $p$ is then an elliptic tail node. A non-trivial automorphism $\sigma$ of $X$ is called an elliptic tail automorphism (with respect to $C_{j}$ ) if $\sigma_{\mid X-C_{j}}$ is the identity.

Theorem 6.5. Let $(X, \eta, \beta)$ be a Prym curve of genus $g \geq 4$. The point $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$ is smooth if and only if $\operatorname{Aut}(X, \eta, \beta)$ is generated by elliptic tail involutions.

Throughout this section, $X$ denotes a quasi-stable curve of genus $g \geq 2$ and $C:=\operatorname{st}(X)$ is its stable model. We denote by $N \subset \operatorname{Sing}(C)$ the set of exceptional nodes and $\Delta:=$ $\operatorname{Sing}(C)-N$. Then $X$ is the support of a Prym curve if and only if $N$ considered as a subgraph of the dual graph $\Gamma(C)$ is eulerian, that is, every vertex of $\Gamma(C)$ is incident to an even number of edges in $N$ (cf. [BCF] Proposition 0.4]).

Locally at a point $[X, \eta, \beta]$, the moduli space $\overline{\mathcal{R}}_{g}$ is isomorphic to the quotient of the versal deformation space $\mathbb{C}_{\tau}^{3 g-3}$ of $(X, \eta, \beta)$ modulo the action of the automorphism group $\operatorname{Aut}(X, \eta, \beta)$. If $\mathbb{C}_{t}^{3 g-3}=\operatorname{Ext}^{1}\left(\Omega_{C}^{1}, \mathcal{O}_{C}\right)$ denotes the versal deformation space of $C$, then the map $\mathbb{C}_{\tau}^{3 g-3} \rightarrow \mathbb{C}_{t}^{3 g-3}$ is given by $t_{i}=\tau_{i}^{2}$ if $\left(t_{i}=0\right) \subset \mathbb{C}_{t}^{3 g-3}$ is the locus where the exceptional node $p_{i} \in N$ persists and $t_{i}=\tau_{i}$ otherwise. The morphism $\pi: \overline{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{M}}_{g}$ is given locally by the map $\mathbb{C}_{\tau}^{3 g-3} / \operatorname{Aut}(X, \eta, \beta) \rightarrow \mathbb{C}_{t}^{3 g-3} / \operatorname{Aut}(C)$. One has the following decomposition of the versal deformation space of $(X, \eta, \beta)$ :

$$
\mathbb{C}_{\tau}^{3 g-3}=\bigoplus_{p_{i} \in N} \mathbb{C}_{\tau_{i}} \oplus \bigoplus_{p_{i} \in \Delta} \mathbb{C}_{\tau_{i}} \oplus \bigoplus_{C_{j} \subset C} H^{1}\left(C_{j}^{\nu}, T_{C_{j}^{v}}\left(-D_{j}\right)\right)
$$

where for a node $p_{i} \in N$ we denote by $\left(\tau_{i}=0\right) \subset \mathbb{C}_{\tau}^{3 g-3}$ the locus where the corresponding exceptional component $E_{i}$ persists, while for a node $p_{i} \in \Delta$ we denote by $\left(\tau_{i}=0\right) \subset \mathbb{C}_{\tau}^{3 g-3}$ the locus of those deformations in which $p_{i}$ persists. Finally, for a component $C_{j} \subset C$ with normalization $C_{j}^{\nu}$, if $D_{j}$ consists of the inverse images of the nodes of $C$ under the normalization map $C_{j}^{v} \rightarrow C_{j}$, the group $H^{1}\left(C_{j}^{v}, T_{C_{j}^{\nu}}\left(-D_{j}\right)\right)$ parameterizes deformations of the pair $\left(C_{j}^{\nu}, D_{j}\right)$. This decomposition is compatible with the decomposition

$$
\mathbb{C}_{t}^{3 g-3}=\left(\bigoplus_{p_{i} \in \operatorname{Sing}(C)} \mathbb{C}_{t_{i}}\right) \oplus\left(\bigoplus_{C_{j}} H^{1}\left(C_{j}^{v}, T_{C_{j}^{\nu}}\left(-D_{j}\right)\right)\right)
$$

as well as with the actions of the automorphism groups on $\mathbb{C}_{\tau}^{3 g-3}$ and $\mathbb{C}_{t}^{3 g-3}$ (see also [Lud, p. 5]). The point $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$ is smooth if and only if the action of $\operatorname{Aut}(X, \eta, \beta)$ on $\mathbb{C}_{\tau}^{3 g-3}$ is generated by quasi-reflections, that is, elements $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ having 1 as an eigenvalue of multiplicity precisely $3 g-4$. Theorem 6.5 follows from the following proposition.

Proposition 6.6. Let $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ be an automorphism of a Prym curve $(X, \eta, \beta)$ of genus $g \geq 4$. Then $\sigma$ acts on $\mathbb{C}_{\tau}^{3 g-3}$ as a quasi-reflection if and only if $X$ has an elliptic tail $C_{j}$ such that $\sigma$ is the elliptic tail involution with respect to $C_{j}$.

Proof. Let $\sigma$ be an elliptic tail involution with respect to $C_{j}$. The induced automorphism $\sigma_{C}$ is an elliptic tail involution of $C$ and acts on the versal deformation space $\mathbb{C}_{t}^{3 g-3}$ of $C$ as $t_{1} \mapsto-t_{1}$ and $t_{i} \mapsto t_{i}, i \neq 1$. Here $t_{1}$ is the coordinate corresponding to the node $p_{1} \in C_{j} \cap \overline{C-C_{j}}$. The node $p_{1}$ being non-exceptional, we have $t_{1}=\tau_{1}$, hence
$\sigma \cdot \tau_{1}=-\tau_{1}$. If $\tau_{i}=t_{i}(i \neq 1)$, then $\sigma \cdot \tau_{i}=\tau_{i}$. For coordinates $t_{i}=\tau_{i}^{2}, \sigma$ is the identity in a neighbourhood of the corresponding exceptional component $E_{i}$, thus $\sigma \cdot \tau_{i}=\tau_{i}$.

Now let $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ act as a quasi-reflection with eigenvalues $\zeta$ and 1 . As in the proof of [Lud, Proposition 2.15], there exists a node $p_{1} \in C$ such that the action of $\sigma$ is given by $\sigma \cdot \tau_{1}=\zeta \tau_{1}$ and $\sigma \cdot \tau_{j}=\tau_{j}$ for $j \neq 1$. When $p_{1} \in N$, the induced automorphism $\sigma_{C}$ acts via $t_{1} \mapsto \zeta^{2} t_{1}$ and $\sigma_{C} \cdot t_{j}=t_{j}$ for $j \neq 1$. If $\zeta^{2} \neq 1$, then $\sigma_{C}$ acts as a quasi-reflection and $p_{1}$ is an elliptic tail node, which contradicts the assumption $p_{1} \in N$. Therefore $\sigma_{C}=\operatorname{Id}_{C}$ and the exceptional component $E_{1}$ over $p_{1}$ is the only component on which $\sigma$ acts non-trivially. The graph $N \subset \Gamma(C)$ is eulerian and there exists a circuit of edges in $N$ containing $p_{1}$ :

By Remark 6.3. $\sigma$ corresponds to an element $\pm\left(\gamma_{j}\right)_{j} \in\{ \pm 1\}^{C C(\widetilde{X})} / \pm 1$. Since $\sigma$ acts non-trivially on $E_{1}$ we find that $\gamma_{1}=-\gamma_{2}$. In particular, there exists $i \neq 1$ such that $\sigma$ acts non-trivially on $E_{i}$. This is a contradiction which shows that the node $p_{1}$ is non-exceptional, $\tau_{1}=t_{1}$ and $\sigma_{C} \cdot t_{1}=\zeta t_{1}$ and $\sigma_{C} \cdot t_{i}=t_{i}$ for $i \neq 1$. Thus $\sigma_{C}$ is an elliptic tail involution of $C$ with respect to an elliptic tail through the node $p_{1}$ and $\zeta=-1$. Since $\sigma$ fixes every coordinate corresponding to an exceptional component of $X$, it follows that $\sigma$ is an elliptic tail involution of $X$.

Theorem 6.7. Fix $g \geq 4$. A point $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$ is a non-canonical singularity if and only if $X$ has an elliptic tail $C_{j}$ with $j$-invariant 0 and $\eta$ is trivial on $C_{j}$.

The proof is similar to that of the analogous statement for $\overline{\mathcal{S}}_{g}$ and we refer to Lud Theorem 3.1] for a detailed outline of the proof and background on quotient singularities. Locally at $[X, \eta, \beta]$, the space $\overline{\mathcal{R}}_{g}$ is isomorphic to a neighbourhood of the origin in $\mathbb{C}_{\tau}^{3 g-3} / \operatorname{Aut}(X, \eta, \beta)$. We consider the normal subgroup $H$ of $\operatorname{Aut}(X, \eta, \beta)$ generated by automorphisms acting as quasi-reflections on $\mathbb{C}_{\tau}^{3 g-3}$. The map $\mathbb{C}_{\tau}^{3 g-3} \rightarrow \mathbb{C}_{\tau}^{3 g-3} / H=$ $\mathbb{C}_{v}^{3 g-3}$ is given by $v_{i}=\tau_{i}^{2}$ if $p_{i}$ is an elliptic tail node and $v_{i}=\tau_{i}$ otherwise. The automorphism group $\operatorname{Aut}(X, \eta, \beta)$ acts on $\mathbb{C}_{v}^{3 g-3}$ and the quotient $\mathbb{C}_{v}^{3 g-3} / \operatorname{Aut}(X, \eta, \beta)$ is isomorphic to $\mathbb{C}_{\tau}^{3 g-3} / \operatorname{Aut}(X, \eta, \beta)$. Since $\operatorname{Aut}(X, \eta, \beta)$ acts on $\mathbb{C}_{v}^{3 g-3}$ without quasireflections the Reid-Shepherd-Barron-Tai criterion applies to this new action.

We fix an automorphism $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ of order $n$ and a primitive $n$-th root of unity $\zeta_{n}$. If the action of $\sigma$ on $\mathbb{C}_{v}^{3 g-3}$ has eigenvalues $\zeta_{n}^{a_{1}}, \ldots, \zeta_{n}^{a_{3 g-3}}$ with $0 \leq a_{i}<n$ for $i=1, \ldots, 3 g-3$, then following [Re2] we define the age of $\sigma$ by

$$
\operatorname{age}\left(\sigma, \zeta_{n}\right):=\frac{1}{n} \sum_{i=1}^{n} a_{i}
$$

We say that $\sigma$ satisfies the Reid-Shepherd-Barron-Tai inequality if age $\left(\sigma, \zeta_{n}\right) \geq 1$. The Reid-Shepherd-Barron-Tai criterion states that $\mathbb{C}_{v}^{3 g-3} / \operatorname{Aut}(X, \eta, \beta)$ has canonical singularities if and only if every $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ satisfies the Reid-Shepherd-Barron-Tai inequality (cf. [Re], [T], [Re2]).
Proof of the "if" part of Theorem 6.7. Let $(X, \eta, \beta)$ be a Prym curve, $C=s t(X)$ and $C_{j} \subset X$ an elliptic tail with $\operatorname{Aut}\left(C_{j}\right)=\mathbb{Z}_{6}$ and assume $\eta_{C_{j}}=\mathcal{O}_{C_{j}}$. We fix an elliptic tail automorphism $\sigma_{C}$ with respect to $C_{j} \subset C$ such that $\operatorname{ord}\left(\sigma_{C}\right)=6$. Then $\sigma_{C}$ acts on $\mathbb{C}_{t}^{3 g-3}$ by $t_{1} \mapsto \zeta_{6} t_{1}, t_{2} \mapsto \zeta_{6}^{2} t_{2}$ for an appropriate sixth root of unity $\zeta_{6}$ and $\sigma \cdot t_{i}=t_{i}$ for $i \neq 1,2$. Here $t_{1}, t_{2} \in \operatorname{Ext}^{1}\left(\Omega_{C}^{1}, \mathcal{O}_{C}\right)$ correspond to smoothing the node $p_{1} \in C_{j} \cap$ $\overline{C-C_{j}}$ and deforming the curve $\left[C_{j}, p_{1}\right] \in \overline{\mathcal{M}}_{1,1}$ respectively. Since $\eta_{C_{j}}=\mathcal{O}_{C_{j}}$, the automorphism $\sigma_{C}$ lifts to an automorphism $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ such that $\sigma_{\overline{X-C_{j}}}$ is the identity. Then $\sigma$ acts on $\mathbb{C}_{\tau}^{3 g-3}$ as $\sigma \cdot \tau_{1}=\zeta_{6} \tau_{1}, \sigma \cdot \tau_{2}=\zeta_{6}^{2} \tau_{2}$ and $\sigma \cdot \tau_{i}=\tau_{i}$ for $i \neq 1,2$. Since $v_{1}=\tau_{1}^{2}$ and $v_{2}=\tau_{2}$, the action of $\sigma$ on $\mathbb{C}_{v}^{3 g-3}$ is $v_{1} \mapsto \zeta_{6}^{2} v_{1}, v_{2} \mapsto \zeta_{6}^{2} v_{2}$ and $v_{i} \mapsto v_{i}, i \neq 1,2$. We compute age $\left(\sigma, \zeta_{6}^{2}\right)=\frac{1}{3}+\frac{1}{3}+0+\cdots+0=\frac{2}{3}<1$, that is, $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$ is a non-canonical singularity. Similarly, an elliptic tail automorphism of order 3 with respect to $C_{j}$ acts via $\tau_{1} \mapsto \zeta_{3}^{2} \tau_{1}, \tau_{2} \mapsto \zeta_{3} \tau_{2}$ and $\tau_{i} \mapsto \tau_{i}, i \neq 1,2$, and then for the action on $\mathbb{C}_{v}^{3 g-3}$ as $v_{1} \mapsto \zeta_{3} v_{1}, v_{2} \mapsto \zeta_{3} v_{2}$ and $v_{i} \mapsto v_{i}$ for $i \neq 1$, 2. This gives a value of $\frac{2}{3}$ for the age.
Suppose that $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$ is a non-canonical singularity. Then there exists an automorphism $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ of order $n$ which acts on $\mathbb{C}_{v}^{3 g-3}$ such that age $\left(\sigma, \zeta_{n}\right)<1$. Let $p_{i_{0}}, p_{i_{1}}=\sigma_{C}\left(p_{i_{0}}\right), \ldots, p_{i_{m-1}}=\sigma_{C}^{m-1}\left(p_{i_{0}}\right)$ be distinct nodes of $C$ which are cyclically permuted by the induced automorphism $\sigma_{C}$ and $p_{i_{j}}$ is not an elliptic tail node. The action of $\sigma$ on the subspace $\bigoplus_{j} \mathbb{C}_{\tau_{i_{j}}} \subset \mathbb{C}_{\tau}^{3 g-3}$ is given by the matrix

$$
B=\left(\begin{array}{cccc}
0 & c_{1} & & \\
\vdots & & \ddots & \\
0 & & & c_{m-1} \\
c_{m} & 0 & \ldots & 0
\end{array}\right)
$$

for appropriate scalars $c_{j} \neq 0$. The pair $((X, \eta, \beta), \sigma)$ is said to be singularity reduced if for every such cycle we have $\prod_{j=1}^{m} c_{j} \neq 1$.

Proposition 6.8 ([|HM], [Lud Proposition 3.6]). There exists a deformation ( $X^{\prime}, \eta^{\prime}, \beta^{\prime}$ ) of $(X, \eta, \beta)$ such that $\sigma$ deforms to an automorphism $\sigma^{\prime} \in \operatorname{Aut}\left(X^{\prime}, \eta^{\prime}, \beta^{\prime}\right)$ and the nodes of every cycle of nodes as above with $\prod_{j=1}^{m} c_{j}=1$ are smoothed. The pair $\left(\left(X^{\prime}, \eta^{\prime}, \beta^{\prime}\right), \sigma^{\prime}\right)$ is then singularity reduced and the action of $\sigma$ on $\mathbb{C}_{v}^{3 g-3}$ and that of $\sigma^{\prime}$ on $\mathbb{C}_{v^{\prime}}^{3 g-3}$ have the same eigenvalues and hence the same age.
We fix a singularity reduced pair $((X, \eta, \beta), \sigma)$ with $n:=\operatorname{ord}(\sigma) \geq 2$ and assume that age $\left(\sigma, \zeta_{n}\right)<1$. We denote this assumption by ( $\star$ ). Using [Lud, Proposition 3.7] we find that if $(\star)$ holds, the induced automorphism $\sigma_{C}$ of $C=s t(X)$ fixes every node with the possible exception of two nodes which are interchanged.

Proposition 6.9. If $(\star)$ holds, then $\sigma_{C}$ fixes all components of the stable model $C$ of $X$.
Proof. Let $C_{i_{0}}, C_{i_{1}}=\sigma_{C}\left(C_{i_{0}}\right), \ldots, C_{i_{m-1}}=\sigma_{C}^{m-1}\left(C_{i_{0}}\right)$ be distinct components of $C$, $\sigma_{C}^{m}\left(C_{i_{0}}\right)=C_{i_{0}}$ and assume that $m \geq 2$. Most of the proof of Proposition 3.8. in Lud] applies to the case of Prym curves and implies that the normalization $C_{i_{0}}^{v}$ is rational and there are exactly three preimages of nodes $p_{1}^{+}, p_{2}^{+}, p_{3}^{+} \in C_{i_{0}}^{v}$ mapping to different nodes of $C$. By [Lud, Proposition 3.7] at least one of $p_{1}, p_{2}, p_{3}$ is fixed by $\sigma_{C}$. If either one or all three nodes are fixed, then $g(C)=2$, impossible. Thus two nodes, say $p_{1}$ and $p_{2}$, are fixed by $\sigma_{C}$ while $p_{3}$ is interchanged with a fourth node $p_{4}$. Interchanging $p_{3}$ and $p_{4}$ gives a contribution of $\frac{1}{2}$ to age $\left(\sigma, \zeta_{n}\right)$. Now consider the action of $\sigma_{C}$ near $p_{1}$ and let $x y=0$ be a local equation of $C$ at $p_{1}$. We have $t_{1}=x y \mapsto y x=t_{1}$ and $\tau_{1} \mapsto \pm \tau_{1}$, where the minus sign is only possible if $p_{1} \in N$. Since $p_{1}$ is not an elliptic tail node and $((X, \eta, \beta), \sigma)$ is singularity reduced, we have $\tau_{1} \mapsto-\tau_{1}$, which gives an additional contribution of $\frac{1}{2}$ to the age, that is, age $\left(\sigma, \zeta_{n}\right) \geq \frac{1}{2}+\frac{1}{2}=1$, contradicting $(\star)$.
Proposition 6.10 ([HM, pp. 28, 36], [Lud, Proposition 3.9]). Assume that ( $\star$ ) holds and denote by $\varphi_{j}=\sigma_{\mid C_{j}^{\nu}}^{v}$ the induced automorphism of the normalization $C_{j}^{v}$ of the irreducible component $C_{j}$ of $C$. Then the pair $\left(C_{j}^{v}, \varphi_{j}\right)$ is one of the following types:
(i) $\varphi_{j}=\mathrm{Id}_{C_{j}^{v}}$ and $C_{j}^{\nu}$ arbitrary.
(ii) $C_{j}^{v}$ is rational and $\operatorname{ord}\left(\varphi_{j}\right)=2,4$.
(iii) $C_{j}^{v}$ is elliptic and $\operatorname{ord}\left(\varphi_{j}\right)=2,4,3,6$.
(iv) $C_{j}^{v}$ is hyperelliptic of genus 2 and $\varphi_{j}$ is the hyperelliptic involution.
(v) $C_{j}^{v}$ is hyperelliptic of genus 3 and $\varphi_{j}$ is the hyperelliptic involution.
(vi) $C_{j}^{v}$ is bielliptic of genus 2 and $\varphi_{j}$ is the associated involution.

The possibility of $\sigma_{C}$ interchanging two nodes does not appear (cf. [Lud, Prop. 3.10]):
Proposition 6.11. Under the assumption ( $\star$ ), the automorphism $\sigma_{C}$ fixes all the nodes of $C$.

Proposition 6.12. Assume ( $\star$ ) holds. Let $C_{j}$ be a component of $C$ with normalization $C_{j}^{v}$, $D_{j}$ the divisor of the marked points on $C_{j}^{v}$ and $\varphi_{j}=\sigma_{\mid C_{j}^{v}}^{v}$. Then $\left(C_{j}^{v}, D_{j}, \varphi_{j}\right)$ is of one of the following types and the contribution to age $\left(\sigma, \zeta_{n}\right)$ coming from $H^{1}\left(C_{j}^{v}, T_{C_{j}^{\nu}}\left(-D_{j}\right)\right) \subset$ $\mathbb{C}_{v}^{3 g-3}$ is at least the following quantity $w_{j}$ :
(i) Identity component: $\varphi_{j}=\mathrm{Id}_{C_{j}^{\nu}}$, arbitrary pair $\left(C_{j}^{v}, D_{j}\right)$ and $w_{j}=0$.
(ii) Elliptic tail: $C_{j}^{v}$ is elliptic, $D_{j}=p_{1}^{+}$and $p_{1}^{+}$is fixed by $\varphi_{j}$.
order 2: $\operatorname{ord}\left(\varphi_{j}\right)=2$ and $w_{j}=0$
order 4: $C_{j}^{v}$ has $j$-invariant $1728, \operatorname{ord}\left(\varphi_{j}\right)=4$ and $w_{j}=\frac{1}{2}$
order 3, 6: $C_{j}^{v}$ has $j$-invariant $0, \operatorname{ord}\left(\varphi_{j}\right)=3$ or 6 and $w_{j}=\frac{1}{3}$
(iii) Elliptic ladder: $C_{j}^{\nu}$ is elliptic, $D_{j}=p_{1}^{+}+p_{2}^{+}$, with $p_{1}^{+}$and $p_{2}^{+}$both fixed by $\varphi_{j}$. order $2: \operatorname{ord}\left(\varphi_{j}\right)=2$ and $w_{j}=\frac{1}{2}$
order 4: $C_{j}^{v}$ has $j$-invariant $1728, \operatorname{ord}\left(\varphi_{j}\right)=4$ and $w_{j}=\frac{3}{4}$
order 3: $C_{j}^{v}$ has $j$-invariant $0, \operatorname{ord}\left(\varphi_{j}\right)=3$ and $w_{j}=\frac{2}{3}$
(iv) Hyperelliptic tail: $C_{j}^{v}$ has genus $2, \varphi_{j}$ is the hyperelliptic involution, $D_{j}$ is of the form $D_{j}=p_{1}^{+}$with $p_{1}^{+}$fixed by $\varphi_{j}$ and $w_{j}=\frac{1}{2}$.
Proof. The proof is along the lines of the proof of Proposition 3.11 in [Lud]. The only difference occurs in the case of a singular elliptic tail on which $\sigma$ acts with order 2. Assume that $C_{j}^{v}$ is rational, $D_{j}=p_{1}^{+}+p_{1}^{-}+p_{2}$, with $\operatorname{ord}\left(\varphi_{j}\right)=2$ which fixes $p_{2}^{+}$ and interchanges $p_{1}^{+}$and $p_{1}^{-}$. If $x y=0$ is an equation for $C$ at $p_{1}$, then $\sigma_{C}$ acts via $t_{1}=x y \mapsto y x=t_{1}$. Since $p_{1}$ is not an elliptic tail node and $((X, \eta, \beta), \sigma)$ is singularity reduced, the node $p_{1}$ must be exceptional and $\sigma \cdot \tau_{1}=-\tau_{1}$.

A deformation of $(X, \eta, \beta)$ over the locus $\left(\tau_{i}=0\right)_{i \neq 1} \subset \mathbb{C}_{\tau}^{3 g-3}$ smooths $p_{1}$. Furthermore, $\sigma$ deforms to an automorphism $\sigma^{\prime}$ of a general Prym curve ( $X^{\prime}, \eta^{\prime}, \beta^{\prime}$ ) over this locus, $\varphi_{j}$ deforms to the involution $\varphi_{j}^{\prime}$ on the smooth elliptic tail $C_{j}^{\prime}$ such that it fixes the line bundle $\eta_{C_{j}^{\prime}}^{\prime}$, and the restrictions of $\sigma$ and $\sigma^{\prime}$ to the complement of $C_{j}$ resp. $C_{j}^{\prime}$ coincide. Over the non-exceptional subcurve $\widetilde{X} \subset X$ we have $\left(\widetilde{\sigma}^{\prime}\right)^{*} \widetilde{\eta}^{\prime} \cong \widetilde{\eta}^{\prime}$. Thus $\sigma \cdot \tau_{1}=\tau_{1}$, which is a contradiction. The case of a singular elliptic tail is thus excluded.

Proposition 6.13. Under the hypothesis ( $\star$ ), the hyperelliptic tail case does not occur.
Proof. Let $C_{j}$ be a genus 2 tail of $C$ and $C_{j^{\prime}}$ the second component through $p_{1}$. The action of $\sigma$ on $H^{1}\left(C_{j}^{v}, T_{C_{j}^{\nu}}\left(-D_{j}\right)\right)$ contributes $\frac{1}{2}$ to the age of $\sigma$ and $C_{j^{\prime}}$ has to be one of the cases of Proposition 6.12 If $C_{j^{\prime}}$ is elliptic, then $g(C)=3$. If $C_{j^{\prime}}$ is a hyperelliptic tail or an elliptic ladder, the action on $H^{1}\left(C_{j^{\prime}}^{v}, T_{C_{j^{\prime}}^{v}}\left(-D_{j^{\prime}}\right)\right)$ contributes at least $\frac{1}{2}$. Therefore $C_{j^{\prime}}$ is an identity component. If $x y=0$ is an equation for $C$ at $p_{1}$, then $\sigma_{C}$ acts via $t_{1}=x y \mapsto-x y=-t_{1}$. The node $p_{1}$ is disconnecting, hence non-exceptional, and it is not an elliptic tail node. Therefore, $v_{1}=\tau_{1}=t_{1}$ and $\sigma$ acts as $\sigma \cdot v_{1}=-v_{1}$. This gives an additional contribution of $\frac{1}{2}$ to the age of $\sigma$, finishing the proof.

Proposition 6.14. In situation ( $\star$ ) the elliptic ladder cases do not occur.
Proof. Let $C_{j}$ be an elliptic ladder of $C$ of order $n_{j}=\operatorname{ord}\left(\varphi_{j}\right)$ and denote by $C_{j^{\prime}}$ resp. $C_{j^{\prime \prime}}$ the second component through the node $p_{1}$ resp. $p_{2}$. Since every elliptic ladder contributes at least $\frac{1}{2}$ to the age, $C_{j^{\prime}}$ and $C_{j^{\prime \prime}}$ can only be elliptic tails or identity components. If both are elliptic tails, then $g(C)=3$, hence we may assume that $C_{j^{\prime}}$ is an identity component. If $x y=0$ is an equation for $C$ at $p_{1}$, then $\sigma_{C}$ acts as $x \mapsto x, y \mapsto \alpha y$ and $t_{1} \mapsto \alpha t_{1}$, where $\alpha$ is a primitive $n_{j}$-th root of 1 . If $p_{1}$ is non-exceptional then $v_{1}=\tau_{1}=t_{1}$ and the space $H^{1}\left(C_{j}^{v}, T_{C_{j}^{\nu}}\left(-D_{j}\right)\right) \oplus \mathbb{C} \cdot v_{1}$ contributes to the age at least

$$
1= \begin{cases}\frac{1}{2}+\frac{1}{2} & \text { if } n_{j}=2, \\ \frac{3}{4}+\frac{1}{4} & \text { if } n_{j}=4, \\ \frac{2}{3}+\frac{1}{3} & \text { if } n_{j}=3\end{cases}
$$

Therefore $p_{1} \in N$. Since $N \subset \Gamma(C)$ is an eulerian subgraph, the node $p_{2}$ is also exceptional, both $p_{1}$ and $p_{2}$ are non-disconnecting and $C_{j^{\prime \prime}}$ is an identity component as well. Moreover $\sigma_{C} \cdot t_{i}=\alpha t_{i}, i=1,2$. Since $v_{i}=\tau_{i}$ and $\tau_{i}^{2}=t_{i}$ for $i=1$, 2, we find that
$\sigma \cdot v_{i}=\alpha_{i} v_{i}, i=1,2$, where $\alpha_{i}$ is a square root of $\alpha$. Therefore, the contribution to the age of $\sigma$ coming from $H^{1}\left(C_{j}^{v}, T_{C_{j}^{\nu}}\left(-D_{j}\right)\right) \oplus \mathbb{C} \cdot v_{1} \oplus \mathbb{C} \cdot v_{2}$ is at least

$$
1= \begin{cases}\frac{1}{2}+\frac{1}{4}+\frac{1}{4} & \text { if } n_{j}=2, \\ \frac{3}{4}+\frac{1}{8}+\frac{1}{8} & \text { if } n_{j}=4, \\ \frac{2}{3}+\frac{1}{6}+\frac{1}{6} & \text { if } n_{j}=3,\end{cases}
$$

and the case of elliptic ladders is excluded.
Proposition 6.15. Under hypothesis ( $\star$ ), the case of an elliptic tail of order 4 does not occur.

Proof. Let $C_{j}$ be an elliptic tail of order 4, and $C_{j^{\prime}}$ another component of $C$ through $p_{1}$. Then $\sigma_{C \mid C_{j}^{\prime}}=\operatorname{Id}_{C_{j}^{\prime}}$ and $\sigma_{C}$ acts as $t_{1}=x y \mapsto \zeta_{4} x y=\zeta_{4} t_{1}$ for a suitable fourth root $\zeta_{4}$ of 1 . Since $p_{1}$ is an elliptic tail node, we have $v_{1}=t_{1}^{2}$ and $\sigma \cdot v_{1}=-v_{1}$. The action of $\sigma$ on $H^{1}\left(C_{j}^{v}, T_{C_{j}^{v}}\left(-D_{j}\right)\right) \oplus \mathbb{C} \cdot v_{1}$ contributes $\geq \frac{1}{2}+\frac{1}{2}=1$ to age $\left(\sigma, \zeta_{4}\right)$, excluding this case.

Proposition 6.16. In situation ( $\star$ ) there has to be at least one elliptic tail of order 3 or 6 .
Proof. Assume to the contrary that every component of $C$ is either an identity component or an elliptic tail of order 2 . The action of $\sigma$ on every space $H^{1}\left(C_{j}^{v}, T_{C_{j}^{\nu}}\left(-D_{j}\right)\right)$ is trivial. If $p_{1}$ is the node of an elliptic tail of order 2, then $\sigma_{C} \cdot t_{1}=-t_{1}$ and we have $v_{1}=\tau_{1}^{2}=t_{1}^{2}$ and $\sigma \cdot v_{1}=v_{1}$. In case $p_{1}$ is non-exceptional but not an elliptic tail node, $\sigma_{C} \cdot t_{1}=t_{1}$. Since $v_{1}=\tau_{1}=t_{1}$, we find that $\sigma$ fixes $v_{1}$. If $p_{1} \in N$, then $\sigma_{C} \cdot t_{1}=t_{1}$ and $v_{1}^{2}=\tau_{1}^{2}=t_{1}$ and $\sigma$ acts as $v_{1} \mapsto \pm v_{1}$. Since age $\left(\sigma, \zeta_{n}\right)<1$, there is exactly one node $p_{1}$ such that $\sigma \cdot v_{1}=-v_{1}$, that is, $\sigma$ acts as quasi-reflection on $\mathbb{C}_{v}^{3 g-3}$, a contradiction.
Proof of the "only if" part of Theorem 6.7. We proved that if $((X, \eta, \beta), \sigma)$ is a singularity reduced pair and age $\left(\sigma, \zeta_{n}\right)<1$, where $n=\operatorname{ord}(\sigma)$, there exists an elliptic tail $C_{j} \subset C$ with $\operatorname{Aut}\left(C_{j}\right)=\mathbb{Z}_{6}$ such that $\operatorname{ord}\left(\sigma_{C_{j}}\right) \in\{3,6\}$. Since $\sigma_{C_{j}}^{*}\left(\eta_{C_{j}}\right) \cong \eta_{C_{j}}$, we find that $\eta_{C_{j}}=\mathcal{O}_{C_{j}}$. Let $((X, \eta, \beta), \sigma)$ be a pair consisting of a Prym curve and an automorphism such that age $\left(\sigma, \zeta_{n}\right)<1$. By Proposition 6.8 we may deform $((X, \eta, \beta), \sigma)$ to a singularity reduced pair $\left(\left(X^{\prime}, \eta^{\prime}, \beta^{\prime}\right), \sigma^{\prime}\right)$ such that the actions of $\sigma$ on $\mathbb{C}_{v}^{3 g-3}$ and $\sigma^{\prime}$ on $\mathbb{C}_{v^{\prime}}^{3 g-3}$ have the same ages. Therefore $X^{\prime}$ has an elliptic tail $C_{j}^{\prime}$ with $\operatorname{Aut}\left(C_{j}^{\prime}\right)=\mathbb{Z}_{6}$ such that $\eta_{C_{j}^{\prime}}^{\prime}$ is trivial and $\sigma^{\prime}$ acts on $C_{j}^{\prime}$ of order 3 or 6 . In the deformation of $(X, \eta, \beta)$ to $\left(X^{\prime}, \eta^{\prime}, \beta^{\prime}\right)$ elliptic tails are preserved, hence $((X, \eta, \beta), \sigma)$ enjoys the same properties.

Remark 6.17. If $\sigma \in \operatorname{Aut}(X, \eta, \beta)$ satisfies the inequality age $\left(\sigma, \zeta_{n}\right)<1$ (with respect to the action on $\mathbb{C}_{v}^{3 g-3}$ ), then $\sigma$ is an elliptic tail automorphism and $\operatorname{ord}(\sigma) \in\{3,6\}$. Indeed, we already know that $\sigma_{C} \in \operatorname{Aut}(C)$ acts with order 3 or 6 on an elliptic tail $C_{j}$. The action of $\sigma$ on $H^{1}\left(C_{j}^{v}, T_{C_{j}^{v}}\left(-D_{j}\right)\right)$ and the $v$-coordinate corresponding to the elliptic tail node on $C_{j}$ contribute at least $\frac{2}{3}$ to age $\left(\sigma, \zeta_{n}\right)$. Thus there is exactly one elliptic tail
of order 3 or 6 and $\sigma_{C}$ is an elliptic tail automorphism of the same order. If $\sigma$ is not an elliptic tail automorphism of $X$, then there exists an exceptional component $E_{1} \subset X$ on which $\sigma$ acts non-trivially. Since $E_{1}$ connects two non-exceptional components of $X$ on which $\sigma$ acts trivially, $\sigma \cdot v_{1}=-v_{1}$, giving a contribution of $\frac{1}{2}$ and an age $\geq \frac{2}{3}+\frac{1}{2} \geq 1$.
Proof of Theorem 6.1. We start with a pluricanonical form $\omega$ on $\overline{\mathcal{R}}_{g}^{\mathrm{reg}}$ and show that $\omega$ lifts to a desingularization of a neighbourhood of every point $[X, \eta, \beta] \in \overline{\mathcal{R}}_{g}$. We may assume that $[X, \eta, \beta]$ is a general non-canonical singularity of $\overline{\mathcal{R}}_{g}$, hence $X=C_{1} \cup_{p} C_{2}$, where $\left[C_{1}, p\right] \in \mathcal{M}_{g-1,1}$ is general and $\left[C_{2}, p\right] \in \mathcal{M}_{1,1}$ has $j$-invariant 0 . Furthermore $\eta_{C_{2}}=\mathcal{O}_{C_{2}}$ and $\eta_{1}:=\eta_{C_{1}} \in \operatorname{Pic}^{0}\left(C_{1}\right)[2]$. We consider the pencil $\phi: \overline{\mathcal{M}}_{1,1} \rightarrow \overline{\mathcal{R}}_{g}$ given by $\phi\left[C^{\prime}, p\right]=\left[C^{\prime} \cup_{p} C_{1}, \eta_{C^{\prime}}=\mathcal{O}_{C^{\prime}}, \eta_{C_{1}}=\eta_{1}\right]$. Since $\phi\left(\overline{\mathcal{M}}_{1,1}\right) \cap \Delta_{0}^{\text {ram }}=\emptyset$, we imitate [HM, pp. 41-44] and construct an explicit open neighbourhood $\overline{\mathcal{R}}_{g} \supset S \supset \phi\left(\overline{\mathcal{M}}_{1,1}\right)$ such that the restriction to $S$ of $\pi: \overline{\mathcal{R}}_{g} \rightarrow \overline{\mathcal{M}}_{g}$ is an isomorphism and every form $\omega \in H^{0}\left(\overline{\mathcal{R}}_{g}^{\text {reg }}, K_{\overline{\mathcal{R}}_{g}^{\text {reg }}}^{\otimes l}\right)$ extends to a resolution $\widehat{S}$ of $S$. For an arbitrary non-canonical singularity we show that $\omega$ extends locally to a desingularization along the lines of Lud Theorem 4.1].
