## A construction of the Deligne-Mumford orbifold

Received March 14, 2005 and in revised form October 12, 2005

#### Abstract

The Deligne-Mumford moduli space is the space $\overline{\mathcal{M}}_{g, n}$ of isomorphism classes of stable nodal Riemann surfaces of arithmetic genus $g$ with $n$ marked points. A marked nodal Riemann surface is stable if and only if its isomorphism group is finite. We introduce the notion of a universal unfolding of a marked nodal Riemann surface and show that it exists if and only if the surface is stable. A natural construction based on the existence of universal unfoldings endows the Deligne-Mumford moduli space with an orbifold structure. We include a proof of compactness. Our proofs use the methods of differential geometry rather than algebraic geometry.

Keywords. Stable curves, Teichmüller theory, Deligne-Mumford orbifolds

## 1. Introduction

According to Grothendieck [7], a moduli space is a space whose elements may be viewed as orbits of a groupoid ${ }^{1}$ In this paper, the main focus is on the Riemann moduli space $\mathcal{M}_{g}$ of (closed) Riemann surfaces of genus $g$ and various related moduli spaces. We characterize the Deligne-Mumford compactification $\overline{\mathcal{M}}_{g}$ by a universal mapping property thus showing that it is (canonically) an orbifold. We also treat the related moduli spaces $\mathcal{M}_{g, n}$ and $\overline{\mathcal{M}}_{g, n}$.

The points in the moduli space $\mathcal{M}_{g}$ are in bijective correspondence with equivalence classes of Riemann surfaces where two Riemann surfaces are equivalent iff there is an isomorphism (holomorphic diffeomorphism) ${ }^{2}$ between them; i.e. the Riemann moduli space is the orbit space of the groupoid whose objects are Riemann surfaces and whose morphisms are these isomorphisms. For applications it is important to refine these groupoids by considering Riemann surfaces with marked points. An object is now a marked Riemann surface of type $(g, n)$, i.e. a Riemann surface of genus $g$ equipped with a sequence of $n$ distinct points in that surface. An isomorphism is an isomorphism of Riemann surfaces which carries the sequence of marked points in the source to the sequence in the target preserving the indexing. The corresponding moduli space is denoted $\mathcal{M}_{g, n}$ and of course $\mathcal{M}_{g, 0}=\mathcal{M}_{g}$.

A Riemann surface is a smooth surface $\Sigma$ equipped with a complex structure $j$. Since any two smooth surfaces of the same genus are diffeomorphic we may define the Riemann moduli space as the orbit space under the action of the diffeomorphism group $\operatorname{Diff}(\Sigma)$ of the space $\mathcal{J}(\Sigma)$ of complex structures $j$ on $\Sigma$ :

$$
\mathcal{M}_{g}:=\mathcal{J}(\Sigma) / \operatorname{Diff}(\Sigma)
$$

The result is independent of the choice of the substrate $\Sigma$ in the sense that any diffeomorphism $f: \Sigma \rightarrow \Sigma^{\prime}$ induces a bijection $\mathcal{J}(\Sigma) \rightarrow \mathcal{J}\left(\Sigma^{\prime}\right)$ and a group isomorphism $\operatorname{Diff}(\Sigma) \rightarrow \operatorname{Diff}\left(\Sigma^{\prime}\right)$ intertwining the group actions. Similarly a marked ${ }^{3}$ Riemann surface is a triple $\left(\Sigma, s_{*}, j\right)$ where $s_{*}$ is a finite sequence of $n$ distinct points of $\Sigma$ (i.e. $s_{*} \in \Sigma^{n} \backslash \Delta$ where $\Delta$ is the "fat" diagonal) so the corresponding moduli space is

$$
\mathcal{M}_{g, n}:=\left(\mathcal{J}(\Sigma) \times\left(\Sigma^{n} \backslash \Delta\right)\right) / \operatorname{Diff}(\Sigma)
$$

This can also be written as

$$
\mathcal{M}_{g, n}=\mathcal{J}(\Sigma) / \operatorname{Diff}\left(\Sigma, s_{*}\right)
$$

where $\operatorname{Diff}\left(\Sigma, s_{*}\right)$ is the subgroup of diffeomorphisms which fix the points of some particular sequence $s_{*}$. Thus in these cases we can replace the groupoid by a group action; the objects are the points of $\mathcal{J}(\Sigma)$.

[^0]An object in a groupoid is called stable iff its automorphism group is finite. A marked Riemann surface of type $(g, n)$ is stable if and only if $n>\chi(\Sigma)$ where $\chi(\Sigma)=2-2 g$ is the Euler characteristic. In this case each automorphism group is finite, but (in the case $g \geq 1$ ) may be nontrivial. However, the only automorphism isotopic to the identity is the identity itself so the identity component $\operatorname{Diff}_{0}(\Sigma)$ of $\operatorname{Diff}(\Sigma)$ acts freely on $\mathcal{J}(\Sigma) \times$ ( $\Sigma^{n} \backslash \Delta$ ). The corresponding orbit space

$$
\mathcal{T}_{g, n}:=\left(\mathcal{J}(\Sigma) \times\left(\Sigma^{n} \backslash \Delta\right)\right) / \operatorname{Diff}_{0}(\Sigma)
$$

is called Teichmïller space. In [4] Earle and Eells showed that the projection $\mathcal{J}(\Sigma) \rightarrow \mathcal{T}_{g}$ is a principal fiber bundle with structure group $\operatorname{Diff}_{0}(\Sigma)$ and that the base $\mathcal{T}_{g}$ is a finitedimensional smooth manifold of real dimension $6 g-6$. In other words, through each $j \in \mathcal{J}(\Sigma)$ there is a smooth slice for the action of $\operatorname{Diff}_{0}(\Sigma)$. (Similar statements hold for $\left.\mathcal{T}_{g, n}.\right)$ The total space $\mathcal{J}(\Sigma)$ is a complex manifold; the tangent space at a point $j \in \mathcal{J}(\Sigma)$ is the space

$$
T_{j} \mathcal{J}(\Sigma)=\Omega_{j}^{0,1}(\Sigma, T M):=\left\{\hat{j} \in \Omega^{0}(\Sigma, \operatorname{End}(T \Sigma)): j \hat{j}+\hat{j} j=0\right\}
$$

of $(0,1)$-forms on $(\Sigma, j)$ with values in the tangent bundle. This tangent space is clearly a complex vector space (the complex structure is $\hat{j} \mapsto j \hat{j}$ ) and it is not hard to show (see e.g. [20] or Section 7] that this almost complex structure on $\mathcal{J}(\Sigma)$ is integrable and that the action admits a holomorphi $4^{4}$ slice through every point. Since the action of $\operatorname{Diff}_{0}(\Sigma)$ is (tautologically) by holomorphic diffeomorphisms of $\mathcal{J}(\Sigma)$, this defines a complex structure on the base $\mathcal{T}_{g}$ which is independent of the choice of the local slice used to define it. Thus $\mathcal{T}_{g}$ is a complex manifold of dimension $3 g-3$. Again, similar results hold for $\mathcal{T}_{g, n}$. Earle and Eells also showed that all three spaces in the fibration

$$
\begin{equation*}
\operatorname{Diff}_{0}(\Sigma) \rightarrow \mathcal{J}(\Sigma) \rightarrow \mathcal{T}_{g} \tag{EE}
\end{equation*}
$$

are contractible so that the fibration is smoothly trivial and has a (globally defined) smooth section. In [3] Earle showed that there is no global holomorphic section of $\mathcal{J}(\Sigma) \rightarrow \mathcal{T}_{g}$. The monograph of Tromba [20] contains a nice exposition of this point of view (and more) and the anthology [6] is very helpful for understanding the history of the subject and other points of view.

Now we take a different point of view. An unfolding is the germ of a pair $\left(\pi_{A}, a_{0}\right)$ where $\pi_{A}: P \rightarrow A$ is a Riemann family and $a_{0}$ is a point of $A$. (The term Riemann family means that $\pi_{A}$ is a proper holomorphic map and $\operatorname{dim}_{\mathbb{C}}(P)=\operatorname{dim}_{\mathbb{C}}(A)+1$. The term germ means that we do not distinguish between $\left(\pi_{A}, a_{0}\right)$ and the unfolding which results by replacing $A$ by a neighborhood of $a_{0}$ in $A$.) The fibers $P_{a}:=\pi^{-1}(a)$ are then complex curves. The fiber $P_{a_{0}}$ is called the central fiber. A morphism of unfoldings is a commutative diagram

[^1]where $\Phi$ and $\phi$ are holomorphic, $\phi\left(a_{0}\right)=b_{0}$ and, for each $a \in A$, the restriction of $\Phi$ to the fiber $P_{a}$ is an isomorphism. Again, this is to be understood in the sense of germs: $\phi$ need only be defined on a neighborhood of $a_{0}$ and two morphisms are the same iff they agree on a smaller neighborhood of $a_{0}$. An unfolding ( $\pi_{B}: Q \rightarrow B, b_{0}$ ) is called universal iff for every other unfolding $\left(\pi_{A}, a_{0}\right)$ every isomorphism $f: P_{a_{0}} \rightarrow Q_{b_{0}}$ extends uniquely to a morphism $(\phi, \Phi)$ from $\left(\pi_{A}, a_{0}\right)$ to $\left(\pi_{B}, b_{0}\right)$. From the uniqueness of the extension it follows that any two universal unfoldings with the same central fiber are isomorphic in the obvious sense.

Now assume that $\pi_{A}$ is a submersion so that the fibers are Riemann surfaces. Using the holomorphic slices for the principal fiber bundle $\mathcal{J}(\Sigma) \rightarrow \mathcal{T}_{g}$ it is not hard to construct a universal unfolding of any Riemann surface of genus $\geq 2$; similar results hold for $\mathcal{T}_{g, n}$ (see Section 8 ).

The spaces $\mathcal{M}_{g, n}$ are not compact. The Deligne-Mumford moduli space $\overline{\mathcal{M}}_{g, n}$ defined in Section 6 is a compactification of $\mathcal{M}_{g, n}$. The objects in the corresponding groupoid are commonly called stable curves of type ( $g, n$ ). Two such curves need not be homeomorphic. This moduli space is still the orbit space of a groupoid but not (in any obvious way) the orbit space of a group action. We will characterize $\overline{\mathcal{M}}_{g, n}$ by the universal mapping property, but we will word the definitions so as to avoid the complexities of algebraic geometry and singularity theory.

It is a well known theorem of algebraic geometry that a complex curve $C$ admits a desingularization $u: \Sigma \rightarrow C$. This means that $\Sigma$ is a Riemann surface and that the restriction of $u$ to the set of regular points of $u$ is a holomorphic diffeomorphism onto the set of smooth points of the curve $C$. The desingularization is unique in the sense that if $u^{\prime}: \Sigma^{\prime} \rightarrow C$ is another desingularization, the holomorphic diffeomorphism $u^{-1} \circ u^{\prime}$ extends to a holomorphic diffeomorphism $\Sigma^{\prime} \rightarrow \Sigma$. A marked complex curve is one which is equipped with a finite sequence of distinct smooth points. A desingularization pulls back the marking to a marking of $\Sigma$. That a marked complex curve $C$ is of type $(g, n)$ means that the arithmetic genus (see Definition 3.6) of $C$ is $g$ and the number of marked points is $n$. A nodal curve is a complex curve with at worst nodal singularities. For a nodal curve the desingularization $u$ is an immersion and the critical points occur in pairs. This equips $\Sigma$ with what we call a nodal structure. In Section 3 we use the term marked nodal Riemann surface to designate a surface $\Sigma$ with these additional structures. A stable curve is a marked nodal curve whose corresponding marked nodal Riemann surface has a finite automorphism group. The main result of this paper extends the universal unfolding construction from the groupoid of stable Riemann surfaces to the groupoid of stable marked nodal Riemann surfaces.

Theorem A. A marked nodal Riemann surface admits a universal unfolding if and only if it is stable.

This theorem is an immediate consequence of Theorems 5.4 and 5.6 below. To avoid the intricacies of singularity theory our precise definitions (see Sections 4 and 5 ) involve only what we call nodal families. However, it is well known that (near its central fiber) an unfolding is a submersion if and only if its central fiber is a smooth complex curve, and is a nodal family if and only if its central fiber is a nodal curve.

Now we describe the proof. First we consider the case of a Riemann surface without marked points or nodal points. In this case the sequence $(E E)$ is a principal bundle if and only if $g \geq 2$, i.e. if and only if any Riemann surface of genus $g$ is stable. Abbreviate

$$
\mathcal{D}_{0}:=\operatorname{Diff}_{0}(\Sigma), \quad \mathcal{J}:=\mathcal{J}(\Sigma), \quad \mathcal{T}:=\mathcal{T}(\Sigma):=\mathcal{J}(\Sigma) / \operatorname{Diff}_{0}(\Sigma)
$$

Thus $\mathcal{T}_{g}:=\mathcal{T}$ is Teichmüller space and the principal fiber bundle $(E E)$ takes the form

$$
\mathcal{D}_{0} \rightarrow \mathcal{J} \rightarrow \mathcal{T}
$$

The associated fiber bundle

$$
\pi_{\mathcal{T}}: \mathcal{Q}:=\mathcal{J} \times_{\mathcal{D}_{0}} \Sigma \rightarrow \mathcal{T}
$$

has fibers isomorphic to $\Sigma$. It is commonly called the universal curve of genus $g$ over Teichmüller space. Choose a Riemann surface ( $\Sigma, j_{0}$ ) and a holomorphic slice $B \subset \mathcal{J}$ through $j_{0}$. Let

$$
\pi_{B}: Q \rightarrow B
$$

be the restriction to $B$ of the pullback of the bundle $\pi_{\mathcal{T}}$ to its total space. As $B$ is a slice, the projection $\pi_{B}$ is a trivial bundle (in the smooth sense). The map $\pi_{B}$ is a holomorphic submersion. In Section 8 we show that it is a universal unfolding of $j_{0}$. Here's why ( $\pi_{B}, j_{0}$ ) is universal. Let $\pi_{A}: P \rightarrow A$ be a holomorphic submersion whose fiber has genus $g$ and whose central fiber over $a_{0} \in A$ is isomorphic to ( $\Sigma, j_{0}$ ). As a smooth map, $\pi_{A}$ is trivial, so after shrinking $A$ we have a smooth local trivialization $\tau: A \times \Sigma \rightarrow P$. Write $\tau_{a}(z):=\tau(a, z)$ for $a \in A$ so $\tau_{a}$ is a diffeomorphism from $\Sigma$ to $P_{a}$. Denote the pull back by $\tau_{a}$ of the complex structure on $P_{a}$ by $j_{a}$, i.e. $\tau_{a}:\left(\Sigma, j_{a}\right) \rightarrow P_{a}$ is an isomorphism. As $B$ is a slice we can modify the trivialization $\tau$ so $j_{a} \in B$. The equation $\phi(a)=j_{a}$ defines a map $\phi: A \rightarrow B$. Using the various trivializations we then get a morphism $(\phi, \Phi)$ from $\pi_{A}$ to $\pi_{B}$. In Section 8 we show that these maps are holomorphic. We also carry out the analogous construction for $\mathcal{T}_{g, n}$.

It is now clear that $\left(\pi_{A}, a_{0}\right)$ is universal if and only if $\phi:\left(A, a_{0}\right) \rightarrow\left(B, b_{0}\right)$ is the germ of a diffeomorphism. By the inverse function theorem this is so if and only if the linear operator $d \phi\left(a_{0}\right): T_{a_{0}} A \rightarrow T_{b_{0}} B$ is invertible. This condition can be formulated as the unique solvability of a partial differential equation on $P_{a_{0}}$; we call an unfolding infinitesimally universal when it satisfies this unique solvability condition. The crucial point is that infinitesimal universality is meaningful even for nodal families, i.e. when there is no analog of the Earle-Eells principal fiber bundle. But we still have the following

Theorem B. A nodal unfolding is universal if and only if it is infinitesimally universal.
This is restated as Theorem 5.4 below. Here is the idea of the proof. Let $\left(\pi_{A}: P \rightarrow A, a_{0}\right)$ and ( $\pi_{B}: Q \rightarrow B, b_{0}$ ) be nodal unfoldings and $f_{0}: P_{a_{0}} \rightarrow Q_{b_{0}}$ be an isomorphism of the central fibers. For simplicity assume there is at most one critical point in each fiber and no marked points. Essentially by the definition of nodal unfolding there is a neighborhood $N$ of the set of critical points such that for $a \in A$ the intersection $N_{a}:=N \cap P_{a}$ admits an isomorphism

$$
N_{a} \cong\left\{(x, y) \in \mathbb{D}^{2}: x y=z\right\}
$$

where $\mathbb{D}$ is the closed unit disk in $\mathbb{C}$ and $z=z(a) \in \mathbb{D}$. Thus if $z(a) \neq 0$ the fiber $N_{a}$ is an annulus whereas if $z(a)=0$ it is a pair of transverse disks. In either case the boundary is a disjoint union $\partial \mathbb{D} \sqcup \partial \mathbb{D}$ of two copies of the circle $S^{1}:=\partial \mathbb{D}$. The map $N \rightarrow A$ is therefore not trivializable as the topology of the fiber changes. However, the bundle $\partial N \rightarrow A$ is trivializable; choose a trivialization $A \times(\partial \mathbb{D} \sqcup \partial \mathbb{D}) \rightarrow \partial N$. Using this trivialization we will define (see Section 11) manifolds of maps

$$
\mathcal{W}:=\bigsqcup_{a \in A} \mathcal{W}_{a}, \quad \mathcal{W}_{a}:=\bigsqcup_{b \in B} \mathcal{W}(a, b), \quad \mathcal{W}(a, b):=\operatorname{Map}\left(\partial N_{a}, Q_{b} \backslash C_{B}\right)
$$

where $C_{B}$ is the set of critical points of $\pi_{B}$ and $\bigsqcup$ denotes disjoint union. Let $\mathcal{U}_{a} \subset \mathcal{W}$ be the set of all maps in $\mathcal{W}_{a}$ which extend to a holomorphic map $N_{a} \rightarrow Q$, and $\mathcal{V}_{a} \subset \mathcal{W}$ be the set of all maps in $\mathcal{W}_{a}$ which extend to a holomorphic map $P_{a} \backslash N_{a} \rightarrow Q$. We will replace $A$ and $\mathcal{W}$ by smaller neighborhoods of $a_{0}$ and $f_{0} \mid \partial N_{a_{0}}$ as necessary. We show that $\mathcal{U}_{a}$ and $\mathcal{V}_{a}$ are submanifolds of $\mathcal{W}_{a}$. It is not too hard to show that the unfolding ( $\pi_{B}, b_{0}$ ) is universal if and only if the manifolds $\mathcal{U}_{a}$ and $\mathcal{V}_{a}$ intersect in a unique point: the morphism $(\phi, \Phi):\left(\pi_{A}, a_{0}\right) \rightarrow\left(\pi_{B}, b_{0}\right)$ is then defined so that this intersection point $\gamma$ lies in the fiber $\mathcal{W}_{\phi(a)}$ and $\Phi_{a}$ is the unique holomorphic map extending $\gamma$. We will see that the unfolding ( $\pi_{B}, b_{0}$ ) is infinitesimally universal if and only if (for all ( $\pi_{A}, a_{0}$ ) and $f_{0}$ ) the corresponding infinitesimal condition

$$
T_{\gamma_{0}} \mathcal{W}_{a_{0}}=T_{\gamma_{0}} \mathcal{U}_{a_{0}} \oplus T_{\gamma_{0}} \mathcal{V}_{a_{0}}
$$

holds where $\gamma_{0}=f_{0} \mid \partial N_{a_{0}}$. This Hardy space decomposition is reminiscent of the construction of the moduli space of holomorphic vector bundles explained by Pressley \& Segal in [17].

We have already explained why smooth marked Riemann surfaces have universal unfoldings. It is now easy to construct a universal unfolding of a stable marked nodal Riemann surface: it is constructed from a universal unfolding for the marked Riemann surface that results by replacing each nodal point by a marked point. Such an unfolding is a triple $\left(\pi, S_{*}, b_{0}\right)$ where $\pi: Q \rightarrow B$ is a nodal family, $S_{*}$ is a sequence of holomorphic sections of $\pi$ corresponding to the marked points, and $b_{0} \in B$. We call a pair ( $\pi, S_{*}$ ) a universal family of type ( $g, n$ ) iff (1) $\left(\pi, S_{*}, b_{0}\right)$ is a universal unfolding for each $b_{0} \in B$ and (2) every marked nodal Riemann surface of type $(g, n)$ occurs as the domain of a desingularization of some fiber $Q_{b}, b \in B$. Theorem 5.3 (openness of transversality) says that if $\left(\pi, S_{*}, b_{0}\right)$ is an infinitesimally universal unfolding then so is $\left(\pi, S_{*}, b\right)$ for $b$ near $b_{0}$. Together with Theorems A and B this implies

Theorem C. If $n>2-2 g$ there exists a universal family of type $(g, n)$.
This is restated as Proposition 6.3 below. It is not asserted that $B$ is connected. Rather, the universal family should be viewed as a generalization of the notion of an atlas for a manifold. This generalization is called an etale groupoid. The Deligne-Mumford orbifold $\overline{\mathcal{M}}_{g, n}$ is then the orbit space of this groupoid and the definitions are arranged so that the orbifold structure is independent of the choice of the universal family used to define it. See Section 6

A consequence of our theorems is that other constructions of the Deligne-Mumford moduli space (and in particular of the Riemann moduli space) which have the universal unfolding property give the same space. However, in the case of a construction where the moduli space is given only a topology (or a notion of convergence of sequences as in [10]) we show that the topology determined by our construction agrees with the topology of the other construction (see Section 13). In Section 14 we prove that our $\overline{\mathcal{M}}_{g, n}$ is compact and Hausdorff by adapting the arguments of the monograph of Hummel [10].

Notation. Throughout, the closed unit disk in the complex plane is denoted by

$$
\mathbb{D}:=\{z \in \mathbb{C}:|z| \leq 1\}
$$

and its interior is denoted by $\operatorname{int}(\mathbb{D}):=\{z \in \mathbb{C}:|z|<1\}$. Thus $S^{1}:=\partial \mathbb{D}$ is the unit circle. Also

$$
\mathbb{A}(r, R):=\{z \in \mathbb{C}: r \leq|z| \leq R\}
$$

denotes the closed annulus with inner radius $r$ and outer radius $R$.

## 2. Orbifold structures

In this section we review orbifolds. Our definitions are arranged so as to suit our ultimate objective of defining an orbifold structure on the Deligne-Mumford moduli space.
2.1. A groupoid is a category in which every morphism is an isomorphism. Let $B$ be the set of objects of a groupoid and $\Gamma$ denote the set of (iso)morphisms. For $a, b \in B$ let $\Gamma_{a, b} \subset \Gamma$ denote the isomorphisms from $a$ to $b$; the group

$$
\Gamma_{a}:=\Gamma_{a, a}
$$

is called the automorphism group ${ }^{5}$ of $a$. The groupoid is called stable iff every automorphism group is finite. Define the source and target maps $s, t: \Gamma \rightarrow B$ by

$$
s(g)=a \text { and } t(g)=b \Leftrightarrow g \in \Gamma_{a, b} .
$$

The map $e: B \rightarrow \Gamma$ which assigns to each object $a$ the identity morphism of $a$ is called the identity section of the groupoid, and the map $i: \Gamma \rightarrow \Gamma$ which assigns to each morphism $g$ its inverse $i(g)=g^{-1}$ is called the inversion map. Define the set $\Gamma_{s} \times_{t} \Gamma$ of composable pairs by

$$
\Gamma_{s} \times_{t} \Gamma=\{(g, h) \in \Gamma \times \Gamma: s(g)=t(h)\} .
$$

The map $m: \Gamma_{s} \times_{t} \Gamma \rightarrow \Gamma$ which assigns to each composable pair the composition $m(g, h)=g h$ is called the multiplication map. The five maps $s, t, e, i, m$ are called the structure maps of the groupoid. Note that

$$
\Gamma_{a, b}=(s \times t)^{-1}(a, b)
$$

We denote the orbit space of the groupoid $(B, \Gamma)$ by $B / \Gamma$ :

$$
B / \Gamma:=\{[b]: b \in B\}, \quad[b]:=\{t(g) \in B: g \in \Gamma, s(g)=b\} .
$$

[^2]2.2. A Lie groupoid is a groupoid $(B, \Gamma)$ such that $B$ and $\Gamma$ are smooth manifolds ${ }^{6}$ the structure maps are smooth, and the map $s: \Gamma \rightarrow B$ (and hence also the map $t=s \circ i$ ) is a submersion. (The latter condition implies that $\Gamma_{s} \times_{t} \Gamma$ is a submanifold of $\Gamma \times \Gamma$ so that the condition that $m$ be smooth is meaningful.) A homomorphism from a Lie groupoid $(B, \Gamma)$ to a Lie groupoid $\left(B^{\prime}, \Gamma^{\prime}\right)$ is a smooth functor, i.e. a pair of smooth maps $B \rightarrow B^{\prime}$ and $\Gamma \rightarrow \Gamma^{\prime}$, both denoted by $\iota$, which intertwine the structure maps:
\[

$$
\begin{gathered}
s^{\prime} \circ \iota=\iota \circ s, \quad t^{\prime} \circ \iota=\iota \circ t, \quad e^{\prime} \circ \iota=\iota \circ e, \\
i^{\prime} \circ \iota=\iota \circ i, \quad m^{\prime} \circ(\iota \times \iota)=\iota \circ m .
\end{gathered}
$$
\]

(The first two of these five conditions imply that $(\iota \times \iota)\left(\Gamma{ }_{s} \times{ }_{t} \Gamma\right) \subset \Gamma^{\prime}{ }_{s^{\prime}} \times_{t^{\prime}} \Gamma^{\prime}$ so that the fifth condition is meaningful.) Similar definitions are used in the complex category reading complex for smooth (for manifolds) and holomorphic for smooth (for maps). A Lie groupoid $(B, \Gamma)$ is called proper if the map $s \times t: \Gamma \rightarrow B \times B$ is proper.
2.3. An etale groupoid is a Lie groupoid $(B, \Gamma)$ such that the map $s: \Gamma \rightarrow B$ (and hence also the map $t=s \circ i$ ) is a local diffeomorphism. A proper etale groupoid is automatically stable. A homomorphism $\iota:(B, \Gamma) \rightarrow\left(B^{\prime}, \Gamma^{\prime}\right)$ of etale groupoids is called a refinement iff the following holds.
(i) The induced map $\iota_{*}: B / \Gamma \rightarrow B^{\prime} / \Gamma^{\prime}$ on orbit spaces is a bijection.
(ii) For all $a, b \in B, \iota$ restricts to a bijection $\Gamma_{a, b} \rightarrow \Gamma_{\iota(a), \iota(b)}^{\prime}$.
(iii) The map on objects (and hence also the map on morphisms) is a local diffeomorphism.

Two proper etale groupoids are called equivalent iff they have a common proper refinement.

Definition 2.4. Fix an abstract groupoid $(\mathcal{B}, \mathcal{G})$. This groupoid is to be viewed as the "substrate" for an additional structure to be imposed; initially it does not even have a topology. Indeed, the definitions are worded so as to allow for the possibility that $\mathcal{B}$ is not even a set but a proper class in the sense of Gödel Bernays set theory (see [12]).

An orbifold structure on the groupoid $(\mathcal{B}, \mathcal{G})$ is a functor $\sigma$ from a proper etale groupoid $(B, \Gamma)$ to $(\mathcal{B}, \mathcal{G})$ such that
(i) $\sigma$ induces a bijection $B / \Gamma \rightarrow \mathcal{B} / \mathcal{G}$ of orbit spaces, and
(ii) for all $a, b \in B, \sigma$ restricts to a bijection $\Gamma_{a, b} \rightarrow \mathcal{G}_{\sigma(a), \sigma(b)}$.

A refinement of orbifold structures is a refinement $\iota:(B, \Gamma) \rightarrow\left(B^{\prime}, \Gamma^{\prime}\right)$ of proper etale groupoids such that $\sigma=\sigma^{\prime} \circ \iota$; as before we say that $\sigma:(B, \Gamma) \rightarrow(\mathcal{B}, \mathcal{G})$ is a refinement of $\sigma^{\prime}:\left(B^{\prime}, \Gamma^{\prime}\right) \rightarrow(\mathcal{B}, \mathcal{G})$. Two orbifold structures are called equivalent iff they have a common refinement. An orbifold is an abstract groupoid $(\mathcal{B}, \mathcal{G})$ equipped with an orbifold structure $\sigma:(B, \Gamma) \rightarrow(\mathcal{B}, \mathcal{G})$.

[^3]Example 2.5. A smooth manifold $M$ is a special case of an orbifold as follows: View $M=: \mathcal{B}$ as a trivial groupoid, i.e. the only morphisms are identity morphisms. Any countable open cover $\left\{U_{\alpha}\right\}_{\alpha \in I}$ on $M$ determines an etale groupoid $(B, \Gamma)$ with

$$
\begin{gathered}
B:=\bigsqcup_{\alpha \in I} U_{\alpha}, \quad \Gamma:=\bigsqcup_{(\alpha, \beta) \in I \times I} U_{\alpha} \cap U_{\beta}, \\
s(\alpha, p, \beta):=(\alpha, p), \quad t(\alpha, p, \beta):=(\beta, p), \quad e(\alpha, p):=(\alpha, p, \alpha), \\
i(\alpha, p, \beta):=(\beta, p, \alpha), \quad m((\beta, p, \gamma),(\alpha, p, \beta)):=(\alpha, p, \gamma) .
\end{gathered}
$$

Here $\bigsqcup$ denotes disjoint union. (The disjoint union $\bigsqcup_{\alpha \in I} X_{\alpha}$ of an indexed collection $\left\{X_{\alpha}\right\}_{\alpha \in I}$ of sets is the set of pairs $(\alpha, x)$ where $\alpha \in I$ and $x \in X_{\alpha}$.) A refinement of open covers in the usual sense determines a refinement of etale groupoids as in 2.3

If $\left\{\phi_{\alpha}, U_{\alpha}\right\}_{\alpha \in I}$ is a countable atlas then an obvious modification of the above construction gives rise to an orbifold structure on $M$ where $B$ is a disjoint union of open subsets of Euclidean space, i.e. a manifold structure is a special case of an orbifold structure.

Example 2.6. A Lie group action $G \rightarrow \operatorname{Diff}(M)$ determines a Lie groupoid $(\mathcal{B}, \mathcal{G})$ where $\mathcal{B}=M, \mathcal{G}=\{(g, a, b) \in G \times M \times M: b=g(a)\}$, and the structure maps are defined by $s(g, a, b):=a, t(g, a, b):=b, e(a):=(\mathrm{id}, a, a), i(g, a, b):=\left(g^{-1}, b, a\right)$, and $m((h, b, c),(g, a, b)):=(h g, a, c)$. The orbit space $\mathcal{B} / \mathcal{G}$ of this groupoid is the same as the orbit space $M / G$ of the group action. The condition that this groupoid be proper is the usual definition of proper group action, i.e. the map $G \times M \rightarrow M \times M:(g, x) \mapsto$ $(x, g(x))$ is proper.

Assume that the action is almost free [meaning that the isotropy group $G_{p}$ of each point of $M$ is finite] and sliceable [meaning that there is a slice through every point of $M$; a slice is a submanifold $S \subset M$ such that there is a neighborhood $U$ of the identity in $G$ with the property that the map $U \times S \rightarrow M:(g, x) \mapsto g(x)$ is a diffeomorphism onto a neighborhood of $S$ in $M$ ]. Now let

$$
B:=\bigsqcup_{\alpha \in I} S_{\alpha}
$$

be a disjoint union of slices such that every orbit passes through at least one slice. Let

$$
\Gamma:=\bigsqcup_{\alpha, \beta \in I} \Gamma_{\alpha \beta}, \quad \Gamma_{\alpha \beta}:=\left\{(g, a, b) \in \mathcal{G}: a \in S_{\alpha}, b \in S_{\beta}\right\}
$$

Then $\Gamma_{\alpha \beta}$ is a submanifold of $\mathcal{G}$. Moreover, if the group action is proper, then the obvious morphism $\sigma:(B, \Gamma) \rightarrow(\mathcal{B}, \mathcal{G})$ is an orbifold structure, and any two such orbifold structures are equivalent. Note that, if $G$ is a discrete group acting properly on $M$, then $S:=\mathcal{B}=M$ is a slice and $\sigma:=\mathrm{id}$ is an orbifold structure.

Example 2.7. Consider the group action where $G:=\mathbb{Z}$ acts on $M:=S^{1}$ by $(k, z) \mapsto$ $e^{2 \pi i k \omega} z$ and $\omega \in \mathbb{R} \backslash \mathbb{Q}$ is irrational. Then the groupoid $(\mathcal{B}, \mathcal{G})$ constructed in Example 2.6 is etale but not proper. Note that the quotient $\mathcal{B} / \mathcal{G}$ is an uncountable set with the trivial topology (two open sets). The inclusion of any open set into $S^{1}$ is a refinement.

Example 2.8. Consider the group action where the multiplicative group $G:=\mathbb{R}^{*}$ of nonzero real numbers acts on $M:=\mathbb{R}^{2} \backslash 0$ by $t \cdot(x, y):=\left(t x, t^{-1} y\right)$. The action is free and sliceable but not proper, and the quotient topology is not Hausdorff (every neighborhood of $\mathbb{R}^{*} \cdot(1,0)$ intersects every neighborhood of $\left.\mathbb{R}^{*} \cdot(0,1)\right)$. The groupoid constructed from the disjoint union $B:=S_{1} \sqcup S_{2}$ of the two slices $S_{1}:=\{1\} \times \mathbb{R}, S_{2}:=\mathbb{R} \times\{1\}$ is not proper. If we extend the group action by adjoining the map $(x, y) \mapsto(y, x)$, the orbit space is $\mathbb{R}$ which is Hausdorff, but the new group action is still not proper.
2.9. Let $(B, \Gamma)$ be a stable etale groupoid, $a, b \in B$, and $g \in \Gamma_{a, b}$. Then there exist neighborhoods $U$ of $a, V$ of $b$ in $B$, and $N$ of $g$ in $\Gamma$ such that $s$ maps $N$ diffeomorphically onto $U$ and $t$ maps $N$ diffeomorphically onto $V$. Define $s_{g}:=s\left|N, t_{g}:=t\right| N$, and $\phi_{g}:=t_{g} \circ s_{g}^{-1}$. Thus $\phi_{g}$ "extends" $g \in \Gamma_{a, b}$ to a diffeomorphism $\phi_{g}: U \rightarrow V$. The following lemma says that when $a=b$ we may choose $U=V$ independent of $g$ and obtain an action

$$
\Gamma_{a} \rightarrow \operatorname{Diff}(U): g \mapsto \phi_{g},
$$

of the finite group $\Gamma_{a}$ on the open set $U$.
Lemma 2.10. Let $(B, \Gamma)$ be a stable etale groupoid and $a \in B$. Then there exists $a$ neighborhood $U$ of a and pairwise disjoint neighborhoods $N_{g}$ (for $g \in \Gamma_{a}$ ) of $g$ in $\Gamma$ such that both $s$ and $t$ map each $N_{g}$ diffeomorphically onto $U$.

Proof. Choose disjoint open neighborhoods $P_{g}$ of $g \in \Gamma_{a}$ such that $s_{g}:=s \mid P_{g}$ and $t_{g}:=t \mid P_{g}$ are diffeomorphisms onto (possibly different) neighborhoods of $a$. By stability the group $\Gamma_{a}$ is finite so there is a neighborhood $V$ of $a$ in $B$ such that $V \subset s\left(P_{g}\right) \cap t\left(P_{g}\right)$ for $g \in \Gamma_{a}$. Define $\phi_{g}: V \rightarrow B$ by $\phi_{g}:=t_{g} \circ s_{g}^{-1}$. Now choose $f, g \in \Gamma_{a}$ and let $h:=m(f, g)$. We show that

$$
\begin{equation*}
\phi_{h}(x)=\phi_{f} \circ \phi_{g}(x) \tag{1}
\end{equation*}
$$

for $x$ in a sufficiently small neighborhood of $a$ in $V$. For such $x$ define $y:=\phi_{g}(x) \in V$, $z:=\phi_{f}(y) \in V, g^{\prime}:=s_{g}^{-1}(x) \in P_{g}$, and $f^{\prime}:=s_{f}^{-1}(y) \in P_{f}$. As $t\left(g^{\prime}\right)=s\left(f^{\prime}\right)=y$ we have $\left(f^{\prime}, g^{\prime}\right) \in \Gamma_{s} \times_{t} \Gamma$, i.e. $h^{\prime}:=m\left(f^{\prime}, g^{\prime}\right)$ is well defined. By continuity, $h^{\prime} \in P_{h}$ and $s\left(h^{\prime}\right)=s\left(g^{\prime}\right)=x$ and $t\left(h^{\prime}\right)=t\left(f^{\prime}\right)=z$, and hence $z=\phi_{h}(x)$ as claimed. Using the finiteness of $\Gamma_{a}$ again we may choose a neighborhood $W$ of $a$ so that (1) holds for all $f, g \in \Gamma_{a}$ and all $x \in W$. Now the intersection

$$
U:=\bigcap_{g \in \Gamma_{a}} \phi_{g}(W) \subset V
$$

satisfies $\phi_{f}(U)=U$ for $f \in \Gamma_{a}$ so $U$ and $N_{g}:=s_{g}^{-1}(U)$ satisfy the conclusions of the lemma.

Corollary 2.11. Let $(B, \Gamma)$ be a stable etale groupoid and $a, b \in B$. Then there exist neighborhoods $U$ and $V$ of a and $b$ in $B$ and pairwise disjoint neighborhoods $N_{f}$ (for $f \in$ $\Gamma_{a, b}$ ) of $f$ in $\Gamma$ such that s maps each $N_{f}$ diffeomorphically onto $U$ and $t$ maps each $N_{f}$
diffeomorphically onto $V$. The etale groupoid is proper if and only if these neighborhoods may be chosen so that in addition

$$
\begin{equation*}
(s \times t)^{-1}(U \times V)=\bigcup_{f \in \Gamma_{a, b}} N_{f} . \tag{*}
\end{equation*}
$$

Proof. Choose disjoint neighborhoods $P_{f}$ of $f \in \Gamma_{a, b}$ such that $s_{f}:=s \mid P_{f}$ and $t_{f}:=$ $t \mid P_{f}$ are diffeomorphisms onto (possibly different) neighborhoods of $a$. Choose $U$ as in Lemma 2.10 so small that $U \subset s\left(P_{f}\right)$ for all $f \in \Gamma_{a, b}$ and define $\phi_{f}: U \rightarrow B$ by

$$
\phi_{f}:=t_{f} \circ s_{f}^{-1} \mid U
$$

Define $N_{f}:=s_{f}^{-1}(U)$. As in Lemma 2.10 we have $\phi_{h}=\phi_{f} \circ \phi_{g}$ for $g \in \Gamma_{a}, f \in \Gamma_{a, b}$, $h:=m(f, g)$, so $t_{h}\left(N_{h}\right)=\phi_{h}(U)=\phi_{f}(U)=t_{f}\left(N_{f}\right)$. Any two elements $h, f \in \Gamma_{a, b}$ satisfy $h=m(f, g)$ for some $g \in \Gamma_{a}$ so $V:=t_{f}\left(N_{f}\right)$ is independent of the choice of $f \in \Gamma_{a, b}$ used to define it. The condition that $s \times t$ is proper means that for any sequence $\left\{f_{\nu} \in \Gamma_{a_{\nu}, b_{v}}\right\}_{\nu}$ such that the sequences $\left\{a_{\nu}\right\}_{\nu}$ and $\left\{b_{\nu}\right\}_{\nu}$ converge to $a$ and $b$ respectively, the sequence $\left\{f_{\nu}\right\}_{\nu}$ has a convergent subsequence. Condition $(*)$ implies this as $f_{\nu}$ must lie in some $N_{f}$ for infinitely many values of $v$. The converse follows easily by an indirect argument.
2.12. Let $(B, \Gamma)$ be an etale groupoid and equip the orbit space $B / \Gamma$ with the quotient topology, i.e. a subset of $B / \Gamma$ is open iff its preimage under the quotient map $\pi: B \rightarrow$ $B / \Gamma$ is open. If $U \subset B$ is open then so is $\pi^{-1}(\pi(U))=\left\{t(g): g \in s^{-1}(U)\right\}$ so $\pi$ is an open map. If $\iota:(B, \Gamma) \rightarrow\left(B^{\prime}, \Gamma^{\prime}\right)$ is a refinement of etale groupoids, then the induced bijection $\iota_{*}: B / \Gamma \rightarrow B^{\prime} / \Gamma^{\prime}$ is a homeomorphism. [The continuity of $\iota_{*}$ follows from the continuity of $\iota$; the openness of $\iota_{*}$ follows from the openness of $\iota$ and the fact that if $U^{\prime} \subset B^{\prime}$ is open then so is $\pi^{\prime-1}\left(\pi^{\prime}\left(U^{\prime}\right)\right)$.] Hence equivalent etale groupoids have homeomorphic orbit spaces. It follows that the topology induced on $\mathcal{B} / \mathcal{G}$ by an orbifold structure $\sigma:(B, \Gamma) \rightarrow(\mathcal{B}, \mathcal{G})$ depends only the equivalence class. This topology is called the orbifold topology.

Corollary 2.13. For a proper etale groupoid the quotient topology on $B / \Gamma$ is Hausdorff.
Proof. In other words, if $\Gamma_{a_{0}, b_{0}}=\emptyset$ then there are neighborhoods $U$ of $a$ and $V$ of $b$ such that $\Gamma(a, b)=\emptyset$ for $a \in U$ and $v \in V$. This is a special case of Corollary 2.11

## 3. Structures on surfaces

The phrase surface means oriented smooth (i.e. $C^{\infty}$ ) manifold of (real) dimension two, not necessarily connected. Unless otherwise specified all surfaces are assume to be closed, i.e. compact and without boundary. The structures we impose on surfaces are complex structures, nodal structures, and point markings. Surfaces equipped with these structures form the objects of a groupoid. The objective of this paper is to equip the orbit space of this groupoid with an orbifold structure.

Definition 3.1. A Riemann surface is a pair $(\Sigma, j)$ where $\Sigma$ is a surface and $j: T \Sigma \rightarrow$ $T \Sigma$ is a smooth complex structure on $\Sigma$ which determines the given orientation of $\Sigma$. Since a complex structure on a surface is necessarily integrable, a Riemann surface may be viewed as a smooth complex curve, i.e. a compact complex manifold of (complex) dimension one. When there is no danger of confusion we denote a Riemann surface and its underlying surface by the same letter.

Definition 3.2. A nodal surface is a pair $(\Sigma, v)$ consisting of a surface $\Sigma$ and a set

$$
v=\left\{\left\{y_{1}, y_{2}\right\},\left\{y_{3}, y_{4}\right\}, \ldots,\left\{y_{2 k-1}, y_{2 k}\right\}\right\}
$$

where $y_{1}, \ldots, y_{2 k}$ are distinct points of $\Sigma$; we also say $v$ is a nodal structure on $\Sigma$. The points $y_{1}, \ldots, y_{2 k}$ are called the nodal points of the structure and the points $y_{2 j-1}$ and $y_{2 j}$ are called equivalent nodal points. The nodal structure should be viewed as an equivalence relation on $\Sigma$ such that every equivalence class consists of either one or two points and only finitely many equivalence classes have two points. Hence we often abbreviate $\Sigma \backslash \bigcup v$ by

$$
\Sigma \backslash \nu:=\Sigma \backslash\left\{y_{1}, y_{2}, y_{3}, y_{4}, \ldots, y_{2 k-1}, y_{2 k}\right\} .
$$

Definition 3.3. A point marking of a surface $\Sigma$ is a sequence

$$
r_{*}=\left(r_{1}, r_{2}, \ldots, r_{n}\right)
$$

of distinct points of $\Sigma$; the points $r_{i}$ are called marked points. A marked nodal surface is a triple $\left(\Sigma, r_{*}, \nu\right)$ where $(\Sigma, \nu)$ is a nodal surface and $r_{*}$ is a point marking of $\Sigma$ such that no marked point $r_{i}$ is a nodal point of $(\Sigma, \nu)$; a special point of the marked nodal surface is a point which is either a nodal point or a marked point.

Definition 3.4. A marked nodal surface $\left(\Sigma, r_{*}, v\right)$ determines a labeled graph called the signature of $\left(\Sigma, r_{*}, \nu\right)$ as follows. The set of vertices of the graph label the connected components of $\Sigma$ and there is one edge connecting vertices $\alpha$ and $\beta$ for every pair of equivalent nodal points with one of the points in $\Sigma_{\alpha}$ and the other in $\Sigma_{\beta}$. More precisely, the number of edges from $\Sigma_{\alpha}$ to $\Sigma_{\beta}$ is the number of pairs $\{x, y\}$ of equivalent nodal points with either $x \in \Sigma_{\alpha}$ and $y \in \Sigma_{\beta}$ or $y \in \Sigma_{\alpha}$ and $x \in \Sigma_{\beta}$. Each vertex $\alpha$ has two labels, the genus of the component $\Sigma_{\alpha}$ denoted by $g_{\alpha}$ and the set of indices of marked points which lie in the component $\Sigma_{\alpha}$.

Remark 3.5. Two marked nodal surfaces are isomorphic if and only if they have the same signature.

Proof. In other words, $\left(\Sigma, r_{*}, \nu\right)$ and ( $\Sigma^{\prime}, r_{*}^{\prime}, v^{\prime}$ ) have the same signature if and only if there is a diffeomorphism $\phi: \Sigma \rightarrow \Sigma^{\prime}$ such that $\nu^{\prime}=\phi_{*} \nu$ where

$$
\phi_{*} v:=\left\{\left\{\phi\left(y_{1}\right), \phi\left(y_{2}\right)\right\},\left\{\phi\left(y_{3}\right), \phi\left(y_{4}\right)\right\}, \ldots,\left\{\phi\left(y_{2 k-1}\right), \phi\left(y_{2 k}\right)\right\}\right\}
$$

and $r_{i}^{\prime}=\phi\left(r_{i}\right)$ for $i=1, \ldots, n=n^{\prime}$. This is because two connected surfaces are diffeomorphic if and only if they have the same genus and any bijection between two finite subsets of a connected surface extends to a diffeomorphism of the ambient manifold.

Definition 3.6. Define the Betti numbers of a graph by the formula

$$
b_{i}:=\operatorname{rank} H_{i}(K), \quad i=0,1,
$$

where $H_{i}(K)$ is the ith homology group of the cell complex $K$. Thus $K$ is connected if and only if $b_{0}=1$ and

$$
b_{0}-b_{1}=\# \text { vertices }-\# \text { edges }
$$

Define the genus of the labeled graph by

$$
g:=b_{1}+\sum_{\alpha} g_{\alpha}
$$

The arithmetic genus of a nodal surface $(\Sigma, v)$ is the genus of the signature of $(\Sigma, \nu)$. Note that the arithmetic genus can be different from the total genus $g^{\prime}:=\sum_{\alpha} g_{\alpha}$.

Definition 3.7. A marked nodal surface $\left(\Sigma, r_{*}, \nu\right)$ is said to be of type $(g, n)$ iff the length of the sequence $r_{*}$ is $n$, the underlying graph $K$ in the signature is connected, and the arithmetic genus of $(\Sigma, v)$ is $g$. A marked nodal Riemann surface $\left(\Sigma, r_{*}, v, j\right)$ is called stable iff its automorphism group

$$
\operatorname{Aut}\left(\Sigma, r_{*}, v, j\right):=\left\{\phi \in \operatorname{Diff}(\Sigma): \phi_{*} j=j, \phi_{*} v=v, \phi\left(r_{*}\right)=r_{*}\right\}
$$

is finite. A stable marked nodal Riemann surface is commonly called a stable curve.
3.8. A marked nodal Riemann surface of type $(g, n)$ is stable if and only if the number of special points in each component of genus zero is at least three and the number of special points in each component of genus one is at least one. This is an immediate consequence of the following:
(i) An automorphism of a surface of genus zero is a Möbius transformation; if it fixes three points it is the identity.
(ii) A surface of genus one is isomorphic to $\mathbb{C} / \Lambda$ where $\Lambda=\mathbb{Z} \oplus \mathbb{Z} \tau$ and $\tau$ lies in the upper half plane.
(iii) The automorphisms of the abelian group $\Lambda$ of form $z \mapsto a z$ where $a \in \mathbb{C} \backslash 0$ form a group of order at most six.
(iv) The automorphism group of a compact Riemann surface of genus greater than one is finite.

The proofs of these well known assertions can be found in any book on Riemann surfaces. It follows that for each pair $(g, n)$ of nonnegative integers there are only finitely many labeled graphs which arise as the signature of a stable marked nodal Riemann surface of type ( $g, n$ ).

Remark 3.9. A marked nodal surface has arithmetic genus zero if and only if each component has genus zero and the graph is a tree. The automorphism group of a stable marked nodal Riemann surface of arithmetic genus zero is trivial.

## 4. Nodal families

In this section we introduce the basic setup which will allow us to define the charts of the Deligne-Mumford orbifold.
4.1. Let $P$ and $A$ be complex manifolds with $\operatorname{dim}_{\mathbb{C}}(P)=\operatorname{dim}_{\mathbb{C}}(A)+1$ and $\pi: P \rightarrow A$ be a holomorphic map. By the holomorphic implicit function theorem a point $p \in P$ is a regular point of $\pi$ if and only if there is a holomorphic coordinate system $\left(t_{1}, \ldots, t_{n}\right)$ defined in a neighborhood of $\pi(p) \in A$, and a function $z$ defined in a neighborhood of $p$ in $P$ such that $\left(z, t_{1} \circ \pi, \ldots, t_{n} \circ \pi\right)$ is a holomorphic coordinate system. In other words, the point $p$ is a regular point if and only if the germ of $\pi$ at $p$ is isomorphic to the germ at 0 of the projection

$$
\mathbb{C}^{n+1} \rightarrow \mathbb{C}^{n}:\left(z, t_{1}, \ldots, t_{n}\right) \mapsto\left(t_{1}, \ldots, t_{n}\right)
$$

Similarly, a point $p \in P$ is a called a nodal point of $\pi$ if and only if the germ of $\pi$ at $p$ is isomorphic to the germ at 0 of the map

$$
\mathbb{C}^{n+1} \rightarrow \mathbb{C}^{n}:\left(x, y, t_{2}, \ldots, t_{n}\right) \mapsto\left(x y, t_{2}, \ldots, t_{n}\right)
$$

i.e. if and only if there are holomorphic coordinates $z, t_{2}, \ldots, t_{n}$ on $A$ at $\pi(p)$ and holomorphic functions $x$ and $y$ defined in a neighborhood of $p$ such that $\left(x, y, t_{2} \circ \pi, \ldots\right.$, $\left.t_{n} \circ \pi\right)$ is a holomorphic coordinate system, $x(p)=y(p)=0$, and $x y=z \circ \pi$. At a regular point $p$ we have $\operatorname{dim}_{\mathbb{C}} \operatorname{ker}(d \pi(p))=1$ and $\operatorname{dim}_{\mathbb{C}} \operatorname{coker}(d \pi(p))=0$ while at a nodal point we have $\operatorname{dim}_{\mathbb{C}} \operatorname{ker}(d \pi(p))=2$ and $\operatorname{dim}_{\mathbb{C}} \operatorname{coker}(d \pi(p))=1$

Definition 4.2. A nodal family is a surjective proper holomorphic map $\pi: P \rightarrow A$ between connected complex manifolds such that $\operatorname{dim}_{\mathbb{C}}(P)=\operatorname{dim}_{\mathbb{C}}(A)+1$ and every critical point of $\pi$ is nodal. We denote the set of critical points of $\pi$ by

$$
C_{\pi}:=\{p \in P: d \pi(p) \text { not surjective }\} .
$$

It intersects each fiber $P_{a}:=\pi^{-1}(a)$ in a finite set. For each regular value $a \in A$ of $\pi$ the fiber $P_{a}$ is a compact Riemann surface. When $a \in A$ is a critical value of $\pi$ we view the fiber $P_{a}$ as a nodal Riemann surface as follows.

By the maximum principle the composition $\pi \circ u$ of $\pi$ with a holomorphic map $u$ : $\Sigma \rightarrow P$ defined on a compact Riemann surface $\Sigma$ must be constant, i.e. $u(\Sigma) \subset P_{a}$ for some $a$. A desingularization of a fiber $P_{a}$ is a holomorphic map $u: \Sigma \rightarrow P$ defined on a compact Riemann surface $\Sigma$ such that
(1) $u^{-1}\left(C_{\pi}\right)$ is finite,
(2) the restriction of $u$ to $\Sigma \backslash u^{-1}\left(C_{\pi}\right)$ maps this set bijectively to $P_{a} \backslash C_{\pi}$.

The restriction of $u$ to $\Sigma \backslash u^{-1}\left(C_{\pi}\right)$ is an isomorphism between this open Riemann surface and $P_{a} \backslash C_{\pi}$ (because it is holomorphic, bijective, and proper).

Lemma 4.3. (i) Every fiber of a nodal family admits a desingularization.
(ii) If $u_{1}: \Sigma_{1} \rightarrow P$ and $u_{2}: \Sigma_{2} \rightarrow P$ are two desingularizations of the same fiber, then the map

$$
u_{2}^{-1} \circ u_{1}: \Sigma_{1} \backslash u_{1}^{-1}\left(C_{\pi}\right) \rightarrow \Sigma_{2} \backslash u_{2}^{-1}\left(C_{\pi}\right)
$$

extends to an isomorphism $\Sigma_{1} \rightarrow \Sigma_{2}$.
(iii) A desingularization $u$ of a fiber of a nodal family is an immersion and the preimage $u^{-1}(p)$ of a critical point $p \in C_{\pi}$ consists of exactly two points.

Proof. Let $\pi: P \rightarrow A$ be a nodal family and $a \in A$. Each $p \in C_{\pi} \cap P_{a}$ has a small neighborhood intersecting $P_{a}$ in two transverse embedded holomorphic disks intersecting at $p$. Define $\Sigma$ set-theoretically as the disjoint union of $P_{a} \backslash C_{\pi}$ with two copies of $P_{a} \cap C_{\pi}$ and use these disks as coordinates; the map $u: \Sigma \rightarrow P_{a}$ is the identity on $P_{a} \backslash C_{\pi}$ and sends each pair of nodal points to the point of $C_{p}$ which gave rise to it. Assertion (ii) follows from the removable singularity theorem for holomorphic functions, and (iii) follows from (ii) and the fact that the maps $x \mapsto(x, 0)$ and $y \mapsto(0, y)$ are immersions.

Remark 4.4. We can construct a canonical desingularization of the fiber by replacing each point $p \in P_{a} \cap C_{\pi}$ by a point for each connected component of $U \backslash\{p\}$ where $U$ is a suitable neighborhood of $p$ in $P_{a}$ and extending the smooth and complex structures in the only way possible.

Definition 4.5. Let $\pi_{A}: P \rightarrow A$ and $\pi_{B}: Q \rightarrow B$ be nodal families. For $a \in A$ and $b \in B$ a bijection $f: P_{a} \rightarrow Q_{b}$ is called a fiber isomorphism iff for some (and hence every) desingularization $u: \Sigma \rightarrow P_{a}$ the map $f \circ u: \Sigma \rightarrow Q_{b}$ is a desingularization. A pseudomorphism from $\pi_{A}$ to $\pi_{B}$ is a commutative diagram

where $\Phi$ and $\phi$ are smooth and, for each $a \in A$, the restriction of $\Phi$ to the fiber $P_{a}$ is a fiber isomorphism. A morphism is a pseudomorphism such that both $\phi$ and $\Phi$ are holomorphic. For $a \in A$ and $b \in B$ the notation

$$
(\Phi, \phi):\left(\pi_{A}, a\right) \rightarrow\left(\pi_{B}, b\right)
$$

indicates that the pseudomorphism $(\Phi, \phi)$ satisfies $\phi(a)=b$.
Lemma 4.6. Let $\pi: P \rightarrow A$ be a nodal family. Then the arithmetic genus (see Definition 3.6) of the fiber $P_{a}$ is a locally constant function of $a \in A$.

Proof. The arithmetic genus is the genus of the surface obtained by removing a small disk about each nodal point and identifying corresponding components. Hence it is equal to the ordinary genus of a regular fiber.

Definition 4.7. A marked nodal family is a pair $\left(\pi, R_{*}\right)$ where $\pi: P \rightarrow A$ is a nodal family and

$$
R_{*}=\left(R_{1}, \ldots, R_{n}\right)
$$

is a sequence of complex submanifolds of $P$ which are pairwise disjoint and such that $\pi \mid R_{i}$ maps $R_{i}$ diffeomorphically onto $A$. It follows that $R_{i}$ does not intersect the set $C_{\pi}$ of critical points. A desingularization $u: \Sigma \rightarrow P$ of a fiber $P_{a}$ of a marked nodal family $\left(\pi, R_{*}\right)$ determines a point marking $r_{*}$ given by the formula

$$
\left\{u\left(r_{i}\right)\right\}=R_{i} \cap P_{a}
$$

for $i=1, \ldots, n$. By Lemma 4.3 any two desingularizations of the same fiber give rise to isomorphic marked nodal Riemann surfaces. Thus the signature (see Definition 3.4) of the fiber $\left(P_{a}, P_{a} \cap R_{*}\right)$ is independent of the choice of the desingularization used to define it. In the context of marked nodal families, the term fiber isomorphism is understood to entail that the bijection $f$ preserves the induced point markings; similarly pseudomorphisms and morphisms of marked nodal families preserve the corresponding point markings. We say that the marked nodal family $\left(\pi, R_{*}\right)$ is of type $(g, n)$ when each fiber is of type $(g, n)$ (see Definition 3.7).

Definition 4.8. A fiber of a marked nodal family $\pi: P \rightarrow A$ is called stable iff its desingularization is stable. A marked nodal family is called stable iff each of its fibers is stable.

Remark 4.9. It is easy to see that stability is an open condition, i.e. every stable fiber has a neighborhood consisting of stable fibers. However, the open set of stable fibers can have unstable fibers in its closure. For example, consider the nodal family ( $\pi,\left(R_{1}, R_{2}, R_{3}\right)$ ) with

$$
P=\left\{([x, y, z], a) \in \mathbb{C} P^{2} \times \mathbb{C}: x y=a z^{2}\right\}
$$

$A=\mathbb{C}, \pi([x, y, z], a)=a, R_{1}=\{[1,0,0]\} \times A, R_{2}=\{[0,1,0]\} \times A$, and $R_{3}=$ $\{([1, a, 1], a): a \in A\}$. The desingularization of the fiber over 0 consists of two components of genus zero and the regular fibers consist of one component of genus zero. The regular fibers all have three marked points and are thus stable; one of the two components of the (desingularized) singular fiber has fewer than three special points and is thus unstable.

## 5. Universal unfoldings

In this section we formulate the most important definitions and theorems of this paper. The key definition is that of a universal unfolding. Once we have established the existence of universal unfoldings, the definition of the orbifold structure on the Deligne-Mumford moduli space (which we carry out in the next section) becomes almost tautological. The most important theorem asserts that an unfolding is universal if and only if it satisfies a suitable infinitesimal conditon (which is easier to verify).

Definition 5.1. A nodal unfolding is a triple $\left(\pi_{B}, S_{*}, b\right)$ consisting of a marked nodal family $\left(\pi_{B}: Q \rightarrow B, S_{*}\right)$ and a point $b \in B$ of the base $B$. The fiber $Q_{b}$ is called
the central fiber of the unfolding and the unfolding is said to be an unfolding of the marked nodal Riemann surface induced by any desingularization of this central fiber. The unfolding is called universal iff for every other nodal unfolding ( $\left.\pi_{A}: P \rightarrow A, R_{*}, a\right)$ and any fiber isomorphism $f: P_{a} \rightarrow Q_{b}$ there is a unique germ of a morphism

$$
(\Phi, \phi):\left(\pi_{A}, a\right) \rightarrow\left(\pi_{B}, b\right)
$$

such that $\Phi\left(R_{i}\right) \subset S_{i}$ for all $i$ and $\Phi \mid P_{a}=f$. The term germ means that $\phi$ is defined in a neighborhood of a in A and $\Phi$ is defined on the preimage of this neighborhood under $\pi_{A}$. The term unique means that if $\left(\Phi^{\prime}, \phi^{\prime}\right)$ is another morphism with the same properties then it agrees with $(\Phi, \phi)$ over a sufficiently small neighborhood of $a$.

Definition 5.2. Let $\left(\pi: Q \rightarrow B, S_{*}, b\right)$ be an unfolding of a marked nodal Riemann surface $\left(\Sigma, s_{*}, v, j\right)$ and $u: \Sigma \rightarrow Q_{b}$ be a desingularization. Let

$$
\mathcal{X}_{u, b}:=\left\{\begin{array}{l|l}
(\hat{u}, \hat{b}) \in \Omega^{0}\left(\Sigma, u^{*} T Q\right) \times T_{b} B & \begin{array}{l}
d \pi(u) \hat{u}=\hat{b}, \hat{u}\left(s_{i}\right) \in T_{u\left(s_{i}\right)} S_{i}, \text { and } \\
u\left(z_{1}\right)=u\left(z_{2}\right) \Rightarrow \hat{u}\left(z_{1}\right)=\hat{u}\left(z_{2}\right)
\end{array}
\end{array}\right\}
$$

and

$$
\mathcal{Y}_{u}:=\left\{\eta \in \Omega^{0,1}\left(\Sigma, u^{*} T Q\right): d \pi(u) \eta=0\right\} .
$$

For $(\hat{u}, \hat{b}) \in \mathcal{X}_{u, b}$ define

$$
D_{u, b}(\hat{u}, \hat{b}):=D_{u} \hat{u}
$$

where $D_{u}: \Omega^{0}\left(\Sigma, u^{*} T Q\right) \rightarrow \Omega^{0,1}\left(\Sigma, u^{*} T Q\right)$ is the linearized Cauchy-Riemann operator. We call the unfolding $\left(\pi, S_{*}, b\right)$ infinitesimally universal iff the operator $D_{u, b}$ : $\mathcal{X}_{u, b} \rightarrow \mathcal{Y}_{u}$ is bijective for some (and hence every) desingularization of the central fiber.

Theorems 5.3, 5.5, and 5.6 which follow are proved in Section 12 below.
Theorem 5.3 (Stability). Let $\left(\pi, S_{*}, b_{0}\right)$ be an infinitesimally universal unfolding. Then $\left(\pi, S_{*}, b\right)$ is infinitesimally universal for $b$ sufficiently near $b_{0}$.

Theorem 5.4 (Universal unfolding). An unfolding $\left(\pi, S_{*}, b\right)$ is universal if and only if it is infinitesimally universal.

Proof. We prove "if" in Section 12. For "only if" we argue as follows. A composition of morphisms (of nodal unfoldings) is again a morphism. The only morphism which is the identity on the central fiber of a universal unfolding is the identity. It follows that any two universal unfoldings of the same marked nodal Riemann surface are isomorphic. By Theorem 5.6 below there is an infinitesimally universal unfolding and by "if" it is universal and hence isomorphic to every other universal unfolding. Any unfolding isomorphic to an infinitesimally universal unfolding is itself infinitesimally universal.

Theorem 5.5 (Uniqueness). Let $\left(\pi_{B}, S_{*}, b_{0}\right)$ be an infinitesimally universal unfolding. Then every pseudomorphism from $\left(\pi_{A}, R_{*}, a_{0}\right)$ to $\left(\pi_{B}, S_{*}, b_{0}\right)$ is a morphism.

Theorem 5.6 (Existence). A marked nodal Riemann surface admits an infinitesimally universal unfolding if and only if it is stable.

Proof. We prove "if" in Section 12, For "only if" we argue as follows. Let ( $\left.\Sigma, s_{*}, v, j\right)$ be a marked nodal Riemann surface. Assume it is not stable. Then either $\Sigma$ has genus one and has no special points or else $\Sigma$ contains a component of genus zero with at most two special points. In either case there is an abelian complex Lie group $A$ (namely $A=\Sigma$ in the former case and $A=\mathbb{C}^{*}$ in the latter) and an effective holomorphic action $A \times \Sigma \rightarrow \Sigma:(a, z) \mapsto a_{\Sigma}(z)$. Let $P:=A \times \Sigma$ and $\pi_{A}$ be the projection on the first factor. If $v: \Sigma \rightarrow Q$ is any desingularization of a fiber $Q_{b}$ of an unfolding $\pi_{B}: Q \rightarrow B$, then $\Phi_{1}(a, z):=v(z)$ and $\Phi_{2}(a, z):=v\left(a_{\Sigma}(z)\right)$ are distinct morphisms which extend the fiber isomorphism $(e, z) \mapsto v(z)$. Hence $\pi_{B}$ is not universal.

## 6. Universal families and the Deligne-Mumford moduli space

In this section we define the orbifold structure on the Deligne-Mumford moduli space. The proof of compactness will be relegated to Section 14. The results we prove in this section are easy consequences of Theorems 5.3 and 5.6
6.1. Throughout this section $g$ and $n$ are nonnegative integers with $n>2-2 g$. Let $\overline{\mathcal{B}}_{g, n}$ denote the groupoid whose objects are stable marked nodal Riemann surfaces of type ( $g, n$ ) and whose morphisms are isomorphisms of marked nodal Riemann surfaces. The Deligne-Mumford moduli space is the orbit space $\overline{\mathcal{M}}_{g, n}$ of this groupoid: a point of $\overline{\mathcal{M}}_{g, n}$ is an equivalence clas ${ }^{7}{ }^{7}$ of objects of $\overline{\mathcal{B}}_{g, n}$ where two objects are equivalent if and only if they are isomorphic. We will introduce a canonical orbifold structure (see Definition 2.4) on this groupoid. The following definition is crucial.

Definition 6.2. A universal marked nodal family of type $(g, n)$ is a marked nodal family ( $\pi_{B}: Q \rightarrow B, S_{*}$ ) satisfying the following conditions.
(1) $\left(\pi_{B}, S_{*}, b\right)$ is a universal unfolding for every $b \in B$.
(2) Every stable marked nodal Riemann surface of type ( $g, n$ ) is the domain of a desingularization of at least one fiber of $\pi_{B}$.
(3) $B$ is second countable (but possibly disconnected).

Proposition 6.3. For every pair $(g, n)$ with $n>2-2 g$ there is a universal marked nodal family.

Proof. By Theorems 5.6, 5.4 and 5.3, each stable marked nodal Riemann surface admits a universal unfolding satisfying (1) and (3). To construct a universal unfolding that also satisfies (2) we must cover $\overline{\mathcal{M}}_{g, n}$ by countably many such families. This is possible because $\overline{\mathcal{M}}_{g, n}$ is a union of finitely many strata, one for each stable signature, and each stratum is a separable topological space.

[^4]Definition 6.4. Let $\left(\pi_{B}: Q \rightarrow B, S_{*}\right)$ be a universal marked nodal family. The associated groupoid is the tuple ( $B, \Gamma, s, t, e, i, m$ ), where $\Gamma$ denotes the set of all triples $(a, f, b)$ such that $a, b \in B$ and $f: Q_{a} \rightarrow Q_{b}$ is a fiber isomorphism, and the structure maps $s, t: \Gamma \rightarrow B, e: B \rightarrow \Gamma, i: \Gamma \rightarrow \Gamma$, and $m: \Gamma_{s} \times_{t} \Gamma \rightarrow \Gamma$ are defined by

$$
\begin{gathered}
s(a, f, b):=a, \quad t(a, f, b):=b, \quad e(a):=(a, \mathrm{id}, a) \\
i(a, f, b):=\left(b, f^{-1}, a\right), \quad m((b, g, c),(a, f, b)):=(a, g \circ f, c)
\end{gathered}
$$

The associated groupoid is equipped with a functor

$$
B \rightarrow \overline{\mathcal{B}}_{g, n}: b \mapsto \Sigma_{b}
$$

to the groupoid $\overline{\mathcal{B}}_{g, n}$ of 6.1 In other words, $\iota_{b}: \Sigma_{b} \rightarrow Q_{b}$ denotes the canonical desingularization defined in Remark 4.4 By definition the induced map

$$
B / \Gamma \rightarrow \overline{\mathcal{M}}_{g, n}:[b]_{B} \mapsto\left[\Sigma_{b}\right]_{\mathcal{B}_{g, n}}, \quad[b]_{B}:=\{t(f): f \in \Gamma, s(f)=b\}
$$

on orbit spaces is bijective. The next theorem asserts that the groupoid $(B, \Gamma)$ equips the moduli space $\overline{\mathcal{M}}_{g, n}$ with an orbifold structure which is independent of the choice of the universal family. This is the orbifold structure on the Deligne-Mumford moduli space.

Theorem 6.5. (i) Let $\left(\pi_{B}: Q \rightarrow B, S_{*}\right)$ be universal as in Definition 6.2 and $(B, \Gamma)$ be the associated groupoid of Definition 6.4 Then there is a unique complex manifold structure on $\Gamma$ such that $(B, \Gamma)$ is a complex etale Lie groupoid with structure maps $s, t, e, i, m$.
(ii) A morphism between universal families $\pi_{0}: Q_{0} \rightarrow B_{0}$ and $\pi_{1}: Q_{1} \rightarrow B_{1}$ induces a refinement $\iota:\left(B_{0}, \Gamma_{0}\right) \rightarrow\left(B_{1}, \Gamma_{1}\right)$ of the associated etale groupoids.
(iii) The orbifold structure on $\overline{\mathcal{M}}_{g, n}$ introduced in Definition 6.4 is independent of the choice of the universal marked nodal family $\left(\pi_{B}, S_{*}\right)$ used to define it.

Proof. We prove (i). Uniqueness is immediate since part of the definition of complex etale Lie groupoid is that $s$ is a local holomorphic diffeomorphism. We prove existence. It follows from the definition of universal unfolding that each triple $\left(a_{0}, f_{0}, b_{0}\right) \in \Gamma$ determines a morphism

for suitable neighborhoods $U \subset B$ of $a_{0}$ and $V \subset B$ of $b_{0}$ such that $\Phi \mid Q_{a_{0}}=f_{0}$. Every such morphism determines a chart $\iota_{\Phi}: U \rightarrow \Gamma$ given by

$$
\iota_{\Phi}(a):=\left(a, \Phi_{a}, \phi(a)\right)
$$

(In this context a chart is a bijection between an open set in a complex manifold and a subset of $\Gamma$.) By construction each transition map between two such charts is the identity.

This defines the manifold structure on $\Gamma$. That the structure maps are holomorphic follows from the identities

$$
\begin{gathered}
s \circ \iota_{\Phi}=\mathrm{id}, \quad t \circ \iota_{\Phi}=\phi, \quad e=\iota_{\mathrm{id}}, \\
i \circ \iota_{\Phi}=\iota_{\Phi^{-1}} \circ \phi, \quad m \circ\left(\iota_{\Psi} \circ \phi \times \iota_{\Phi}\right)=\iota_{\Psi \circ \Phi} .
\end{gathered}
$$

This proves (i).
We prove (ii). If $(\phi, \Phi)$ is a morphism from $\pi_{0}$ to $\pi_{1}$ then the refinement $\iota:\left(B_{0}, \Gamma_{0}\right)$ $\rightarrow\left(B_{1}, \Gamma_{1}\right)$ of (ii) is given by

$$
\left(a_{0}, f_{0}, b_{0}\right) \mapsto\left(\phi\left(a_{0}\right), \Phi_{b_{0}} \circ f_{0} \circ \Phi_{a_{0}}^{-1}, \phi\left(b_{0}\right)\right)
$$

This proves (ii).
We prove (iii). Let $\pi_{0}: Q_{0} \rightarrow B_{0}$ and $\pi_{1}: Q_{1} \rightarrow B_{1}$ be universal families. For each $b \in B_{0}$ choose a neighborhood $U_{b} \subset B_{0}$ of $b$ and a morphism $\Phi_{b}: Q_{0} \mid U_{b} \rightarrow Q_{1}$. Cover $B_{0}$ by countably many such neighborhoods $U_{b_{i}}$. Then the disjoint union $B$ of the nodal families $Q_{0} \mid U_{b_{i}}$ defines another universal family $\pi: Q \rightarrow B$ equipped with morphisms to both $\pi_{0}$ and $\pi_{1}$ (to $\pi_{0}$ by inclusion and to $\pi_{1}$ by construction). Now each morphism of universal families induces a refinement of the corresponding orbifold structures.

Theorem 6.6. Let ( $\pi_{B}: Q \rightarrow B, S_{*}$ ) be a universal family. Then the etale groupoid $(B, \Gamma)$ constructed in Definition 6.4 is proper and the quotient topology on $B / \Gamma$ is compact.

Proof. See Section 14 below.
Example 6.7. Assume $g=0$. Then the moduli space $\overline{\mathcal{M}}_{0, n}$ of marked nodal Riemann surfaces of genus zero (called the Grothendieck-Knudsen compactification) is a compact connected complex manifold (Knudsen's theorem). In our formulation this follows from the fact that the automorphism group of each marked nodal Riemann surface of genus zero consists only of the identity. In [16, Appendix D] the complex manifold structure on $\overline{\mathcal{M}}_{0, n}$ is obtained from an embedding into a product of 2 -spheres via cross ratios. That the manifold structure in [16] agrees with ours follows from the fact that the projection $\pi: \overline{\mathcal{M}}_{0, n+1} \rightarrow \overline{\mathcal{M}}_{0, n}$ (with the complex manifold structures of [16]) is a universal family as in Definition 6.2 .

## 7. Complex structures on surfaces

## The sphere

In preparation for the construction of universal unfoldings (without nodes and marked points) we review the space of complex structures on a Riemann surface $\Sigma$ in this and the following two sections. This section treats the case of genus zero. Denote by $\mathcal{J}\left(S^{2}\right)$ the space of complex structures on $S^{2}$ that induce the standard orientation and by $\operatorname{Diff}_{0}\left(S^{2}\right)$ the group of orientation preserving diffeomorphisms of $S^{2}$.

Theorem 7.1. There is a fibration

where the inclusion $\operatorname{PSL}_{2}(\mathbb{C}) \rightarrow \operatorname{Diff}_{0}\left(S^{2}\right)$ is the action by Möbius transformations and the projection $\operatorname{Diff}_{0}\left(S^{2}\right) \rightarrow \mathcal{J}\left(S^{2}\right)$ sends $\phi$ to $\phi^{*} i$.
The theorem asserts that the map $\operatorname{Diff}_{0}\left(S^{2}\right) \rightarrow \mathcal{J}\left(S^{2}\right)$ has the path lifting property for smooth paths and that the lifting depends smoothly on the path. One consequence of this, as observed in [4], is the celebrated theorem of Smale [19] which asserts that $\operatorname{Diff}_{0}\left(S^{2}\right)$ retracts onto $\mathrm{SO}(3)$. Another consequence is that, up to diffeomorphism, there is a unique complex structure on the 2 -sphere. Yet another consequence is that a proper holomorphic submersion whose fibers have genus zero is holomorphically locally trivial. (See Theorem 8.9)
Proof of Theorem 7.1] Choose a smooth path [0, 1] $\rightarrow \mathcal{J}\left(S^{2}\right): t \mapsto j_{t}$. We will find an isotopy $t \mapsto \psi_{t}$ of $S^{2}$ such that

$$
\begin{equation*}
\psi_{t}^{*} j_{t}=j_{0} \tag{2}
\end{equation*}
$$

Suppose that the unknown isotopy $\psi_{t}$ is generated by a smooth family of vector fields $\xi_{t} \in \operatorname{Vect}\left(S^{2}\right)$ via

$$
\frac{d}{d t} \psi_{t}=\xi_{t} \circ \psi_{t}, \quad \psi_{0}=\mathrm{id}
$$

Then (2) is equivalent to $\psi_{t}^{*}\left(\mathcal{L}_{\xi_{t}} j_{t}+\hat{j}_{t}\right)=0$ and hence to

$$
\begin{equation*}
\mathcal{L}_{\xi_{t}} j_{t}+\hat{j}_{t}=0 \tag{3}
\end{equation*}
$$

where ${\hat{j_{t}}}_{t}:=\frac{d}{d t} j_{t} \in C^{\infty}\left(\operatorname{End}\left(T S^{2}\right)\right)$. As usual we can think of $\hat{j}_{t}$ as a $(0,1)$-form on $S^{2}$ with values in the complex line bundle

$$
E_{t}:=\left(T S^{2}, j_{t}\right)
$$

The vector field $\xi_{t}$ is a section of this line bundle. This line bundle is holomorphic and its Cauchy-Riemann operator

$$
\bar{\partial}_{j_{t}}: C^{\infty}\left(E_{t}\right) \rightarrow \Omega^{0,1}\left(E_{t}\right)
$$

has the form

$$
\bar{\partial}_{j_{t}} \eta=\frac{1}{2}\left(\nabla \eta+j_{t} \circ \nabla \eta \circ j_{t}\right)
$$

where $\nabla$ is the Levi-Civita connection of the Riemannian metric $\omega\left(\cdot, j_{t} \cdot\right)$ on $S^{2}$ and $\omega \in$ $\Omega^{2}\left(S^{2}\right)$ denotes the standard volume form. Now, for every vector field $\eta \in \operatorname{Vect}\left(S^{2}\right)$, we have

$$
\begin{aligned}
\left(\mathcal{L}_{\xi_{t}} j_{t}\right) \eta & =\mathcal{L}_{\xi_{t}}\left(j_{t} \eta\right)-j_{t} \mathcal{L}_{\xi_{t}} \eta=\left[j_{t} \eta, \xi_{t}\right]-j_{t}\left[\eta, \xi_{t}\right] \\
& =\nabla_{\xi_{t}}\left(j_{t} \eta\right)-\nabla_{j_{t}} \xi_{t}-j_{t} \nabla_{\xi_{t}} \eta+j_{t} \nabla_{\eta} \xi_{t} \\
& =j_{t} \nabla_{\eta} \xi_{t}-\nabla_{j_{t} \eta} \eta \xi_{t}=2 j_{t}\left(\bar{\partial}_{j_{t}} \xi_{t}\right)(\eta) .
\end{aligned}
$$

The penultimate equality uses the fact that $j_{t}$ is integrable and so $\nabla j_{t}=0$. Hence equation (3) can be expressed in the form

$$
\begin{equation*}
\bar{\partial}_{j_{t}} \xi_{t}=\frac{1}{2} j_{t} \hat{j}_{t} . \tag{4}
\end{equation*}
$$

Now the line bundle $E_{t}$ has Chern number $c_{1}\left(E_{t}\right)=2$ and hence, by the Riemann-Roch theorem, the Cauchy-Riemann operator $\bar{\partial}_{j_{t}}$ has real Fredholm index six and is surjective for every $t$. Denote by

$$
\bar{\partial}_{j_{t}}^{*}: \Omega^{0,1}\left(E_{t}\right) \rightarrow C^{\infty}\left(E_{t}\right)
$$

the formal $L^{2}$-adjoint operator of $\bar{\partial}_{j_{t}}$. By elliptic regularity, the formula

$$
\xi_{t}:=\frac{1}{2} \bar{\partial}_{\xi_{t}}^{*}\left(\bar{\partial}_{j_{t}} \bar{\partial}_{j_{t}}^{*}\right)^{-1}\left(j_{t} \hat{j}_{t}\right)
$$

defines a smooth family of vector fields on $S^{2}$ and this family obviously satisfies (4). Hence the isotopy $\psi_{t}$ generated by $\xi_{t}$ satisfies (2).
Lemma 7.2. Let $\mathbb{C} \rightarrow \mathcal{J}\left(S^{2}\right): s+$ it $\mapsto j_{s, t}$ be holomorphic and $\mathbb{C} \rightarrow \operatorname{Diff}\left(S^{2}\right)$ : $s+i t \mapsto \phi_{s, t}$ be the unique family of diffeomorphisms satisfying

$$
\phi_{s, t}^{*} j_{s, t}=i, \quad \phi_{s, t}(0)=0, \quad \phi_{s, t}(1)=1, \quad \phi_{s, t}(\infty)=\infty .
$$

Then the map

$$
\mathbb{C} \times S^{2} \rightarrow \mathbb{C} \times S^{2}:(s+i t, z) \mapsto\left(s+i t, \phi_{s, t}(z)\right)
$$

is holomorphic with respect to the standard complex structure at the source and the complex structure

$$
J(s, t, z):=\left(\begin{array}{cc}
i & 0 \\
0 & j_{s, t}(z)
\end{array}\right)
$$

at the target.
Proof. Define $\xi_{s, t}, \eta_{s, t} \in \operatorname{Vect}\left(S^{2}\right)$ by

$$
\partial_{s} \phi_{s, t}=\xi_{s, t} \circ \phi_{s, t}, \quad \partial_{y} \phi_{s, t}=\eta_{s, t} \circ \phi_{s, t} .
$$

Differentiating the identity $\phi_{s, t}^{*} j_{s, t}=i$ gives $\partial_{s} j+\mathcal{L}_{\xi} j=\partial_{t} j+\mathcal{L}_{\eta} j=0$. Since $s+i t \mapsto$ $j_{s, t}$ is holomorphic we have

$$
0=\partial_{s} j+j \partial_{t} j=-\mathcal{L}_{\xi} j-j \mathcal{L}_{\eta} j=-\mathcal{L}_{\xi+j \eta} j
$$

where the last equality uses the integrability of $j$. Thus $\xi_{s, t}+j_{s, t} \eta_{s, t}$ is a holomorphic vector field vanishing at three points so $\xi_{s, t}+j_{s, t} \eta_{s, t}=0$ for all $s, t$. Hence by definition of $\xi$ and $\eta$ we have

$$
\partial_{s} \phi+j \partial_{t} \phi=0
$$

as required.

## The torus

Continuing the preparatory discussion of the previous section we treat the case of genus one. Denote by $\mathcal{J}\left(\mathbb{T}^{2}\right)$ the space of complex structures on the 2-torus $\mathbb{T}^{2}:=\mathbb{R}^{2} / \mathbb{Z}^{2}$ that induce the standard orientation and by $\operatorname{Diff}\left(\mathbb{T}^{2}\right)$ the group of diffeomorphisms of $\mathbb{T}^{2}$
that induce the identity on homology. Denote the elements of the upper half plane $\mathbb{H}$ by $\lambda=\lambda_{1}+i \lambda_{2}$ and consider the map $j: \mathbb{H} \rightarrow \mathcal{J}\left(\mathbb{T}^{2}\right)$ given by

$$
j(\lambda):=\frac{1}{\lambda_{2}}\left(\begin{array}{cc}
-\lambda_{1} & -\lambda_{1}^{2}-\lambda_{2}^{2}  \tag{5}\\
1 & \lambda_{1}
\end{array}\right) .
$$

Thus $j(\lambda)$ is the pullback of the standard complex structure under the diffeomorphism

$$
f_{\lambda}: \mathbb{T}^{2} \rightarrow \frac{\mathbb{C}}{\mathbb{Z}+\lambda \mathbb{Z}}, \quad f_{\lambda}(x, y):=x+\lambda y
$$

A straightforward calculation shows that the map $j: \mathbb{H} \rightarrow \mathcal{J}\left(\mathbb{T}^{2}\right)$ is holomorphic as is the map

$$
(\lambda, z+\mathbb{Z}+\lambda \mathbb{Z}) \mapsto\left(j(\lambda), f_{\lambda}^{-1}(z)+\mathbb{Z}^{2}\right)
$$

from $\{(\lambda, z+\mathbb{Z}+\lambda \mathbb{Z}): \lambda \in \mathbb{H}, z \in \mathbb{C}\}$ to $\mathcal{J}\left(\mathbb{T}^{2}\right) \times \mathbb{T}^{2}$. The next theorem shows that the map $j: \mathbb{H} \rightarrow \mathcal{J}\left(\mathbb{T}^{2}\right)$ is a global slice for the action of $\operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right)$.
Theorem 7.3. There is a proper fibration

$$
\begin{gathered}
\mathbb{T}^{2} \rightarrow \operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right) \times \mathbb{H} \\
\downarrow \\
\mathcal{J}\left(\mathbb{T}^{2}\right)
\end{gathered}
$$

where the inclusion $\mathbb{T}^{2} \rightarrow \operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right)$ is the action by translations and the projection $\operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right) \times \mathbb{H} \rightarrow \mathcal{J}\left(\mathbb{T}^{2}\right)$ sends $(\phi, \lambda)$ to $\phi^{*} j_{\lambda}$.
The theorem asserts that the map $\operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right) \times \mathbb{H} \rightarrow \mathcal{J}\left(\mathbb{T}^{2}\right)$ has the path lifting property for smooth paths and that the lifting depends smoothly on the path. One consequence of this is that $\operatorname{Diff}\left(\mathbb{T}^{2}\right)$ retracts onto $\mathbb{T}^{2}$. Another consequence is that every complex structure on $\mathbb{T}^{2}$ is diffeomorphic to $j_{\lambda}$ for some $\lambda \in \mathbb{H}$.
Proof of Theorem 7.3. The uniformization theorem asserts that for every $j \in \mathcal{J}\left(\mathbb{T}^{2}\right)$ there is a unique volume form $\omega_{j} \in \Omega^{2}\left(\mathbb{T}^{2}\right)$ with $\int_{\mathbb{T}^{2}} \omega_{j}=1$ such that the metric $g_{j}=\omega_{j}(\cdot, j \cdot)$ has constant curvature zero. (A proof can be based on the Kazdan-Warner equation.) Hence it follows from the Cartan-Ambrose-Hicks theorem that, for every positive real number $\mu$, there is an orientation preserving diffeomorphism $\psi_{j}: \mathbb{C} \rightarrow \mathbb{R}^{2}$, unique up to composition with a rotation, such that

$$
\psi_{j}^{*} g_{j}=\mu g_{0}, \quad \psi(0)=0
$$

Here $g_{0}$ denotes the standard metric on $\mathbb{C}$. We can choose $\mu$ and the rotation such that $\psi_{j}(1)=(1,0)$. This determines $\psi_{j}$ (and $\mu$ ) uniquely. The orientation preserving condition shows that $\lambda_{j}:=\psi_{j}(i) \in \mathbb{H}$. Moreover, it follows from the invariance of $g_{j}$ under the action of $\mathbb{Z}^{2}$ that

$$
\psi_{j}(\mathbb{Z}+\lambda \mathbb{Z})=\mathbb{Z}^{2}
$$

Hence $\psi_{j}$ induces an isometry of flat tori $\left(\mathbb{C} / \mathbb{Z}+\lambda_{j} \mathbb{Z}, g_{0}\right) \rightarrow\left(\mathbb{T}^{2}, g_{j}\right)$ which will still be denoted by $\psi_{j}$. Let $\phi_{j}$ be the precomposition of this isometry with the map
$\mathbb{T}^{2} \rightarrow \mathbb{C}^{2} / \mathbb{Z}+\lambda_{j} \mathbb{Z}:(x, y) \mapsto x+\lambda_{j} y$. Then $\phi_{j} \in \operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right)$ and $\phi_{j}^{*} j=j\left(\lambda_{j}\right)$. Thus we have proved that the map

$$
\operatorname{Diff}_{00}\left(\mathbb{T}^{2}\right) \times \mathbb{H} \rightarrow \mathcal{J}\left(\mathbb{T}^{2}\right):(\phi, \lambda) \mapsto \phi^{*} j(\lambda)
$$

is a bijection, where $\operatorname{Diff}_{00}\left(\mathbb{T}^{2}\right)$ is the subgroup of all diffeomorphisms $\phi \in \operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right)$ that satisfy $\phi(0)=0$. That the map $\operatorname{Diff}_{00}\left(\mathbb{T}^{2}\right) \times \mathbb{H} \rightarrow \mathcal{J}\left(\mathbb{T}^{2}\right)$ is actually a diffeomorphism follows by examining the linearized operator at points $(\phi, \lambda)$ with $\phi=$ id and noting that it is a bijection (between suitable Sobolev completions). This proves the theorem.

## Surfaces of higher genus

Continuing the preparatory discussion of the previous two sections we treat the case of genus bigger than one. Let $\Sigma$ be a compact connected oriented 2-manifold of genus $g>1$ and $\mathcal{J}(\Sigma)$ be the Fréchet manifold of complex structures $j$ on $\Sigma$, i.e. $j$ is an automorphism of $T \Sigma$ such that $j^{2}=-\mathbb{1}$. The identity component $\operatorname{Diff}_{0}(\Sigma)$ of the group of orientation preserving diffeomorphisms acts on $\mathcal{J}(\Sigma)$ by $j \mapsto \phi^{*} j$. The orbit space

$$
\mathcal{T}(\Sigma):=\mathcal{J}(\Sigma) / \operatorname{Diff}_{0}(\Sigma)
$$

is called the Teichmüller space of $\Sigma$. For $j \in \mathcal{J}(\Sigma)$ the tangent space $T_{j} \mathcal{J}(\Sigma)$ is the space of endomorphisms $\hat{j} \in \Omega^{0}(\Sigma, \operatorname{End}(T \Sigma))$ that anti-commute with $j$, i.e. $j \hat{j}+\hat{j} j$ $=0$. Thus

$$
T_{j} \mathcal{J}(\Sigma)=\Omega_{j}^{0,1}(\Sigma, T \Sigma)
$$

Define an almost complex structure on $\mathcal{J}(\Sigma)$ by the formula $\hat{j} \mapsto j \hat{j}$. The next theorem shows that $\mathcal{T}(\Sigma)$ is a complex manifold of dimension $3 g-3$.

Theorem 7.4. For every $j_{0} \in \mathcal{J}(\Sigma)$ there exists a holomorphic local slice through $j_{0}$. More precisely, there is an open neighborhood $B$ of zero in $\mathbb{C}^{3 g-3}$ and a holomorphic map $\iota: B \rightarrow \mathcal{J}(\Sigma)$ such that the map

$$
B \times \operatorname{Diff}_{0}(\Sigma) \rightarrow \mathcal{J}(\Sigma):(b, \phi) \mapsto \phi^{*} \iota(b)
$$

is a diffeomorphism onto a neighborhood of the orbit of $j_{0}$.
Proof. We first show that each orbit of the action of $\operatorname{Diff}_{0}(\Sigma)$ is an almost complex submanifold of $\mathcal{J}(\Sigma)$. (The complex structure on $\mathcal{J}(\Sigma)$ is integrable because $\mathcal{J}(\Sigma)$ is the space of sections of a bundle over $\Sigma$ whose fibers are complex manifolds. However, we shall not use this fact.) The Lie algebra of $\operatorname{Diff}_{0}(\Sigma)$ is the space of vector fields

$$
\operatorname{Vect}(\Sigma)=\Omega^{0}(\Sigma, T \Sigma)
$$

Its infinitesimal action on $\mathcal{J}(\Sigma)$ is given by

$$
\operatorname{Vect}(\Sigma) \rightarrow T_{j} \mathcal{J}(\Sigma): \xi \mapsto \mathcal{L}_{\xi} j=2 j \bar{\partial}_{j} \xi
$$

Thus the tangent space of the orbit of $j$ is the image of the Cauchy-Riemann operator $\bar{\partial}_{j}: \Omega^{0}(\Sigma, T \Sigma) \rightarrow \Omega_{j}^{0,1}(\Sigma, T \Sigma)$. Since $j$ is integrable the operator $\bar{\partial}_{j}$ is complex linear and so its image is invariant under multiplication by $j$.

By the Riemann-Roch theorem the operator $\bar{\partial}_{j}$ has complex Fredholm index $3-3 g$. It is injective because its kernel is the space of holomorphic sections of a holomorphic line bundle of negative degree. Hence its cokernel has dimension $3 g-3$. Let $B \subset$ $\Omega_{j_{0}}^{0,1}(\Sigma, T \Sigma)$ be an open neighborhood of zero in a complex subspace of dimension $3 g-3$ which is a complement of the image of $\bar{\partial}_{j_{0}}$ and assume that $\mathbb{1}+\eta$ is invertible for every $\eta \in B$. Define $\iota: B \rightarrow \mathcal{J}(\Sigma)$ by

$$
\iota(\eta):=(\mathbb{1}+\eta)^{-1} j_{0}(\mathbb{1}+\eta)
$$

Then

$$
d \iota(\eta) \hat{\eta}=\left[\iota(\eta),(\mathbb{1}+\eta)^{-1} \hat{\eta}\right]
$$

and an easy calculation shows that $\iota$ is holomorphic, i.e. $d \iota(\eta) j_{0} \hat{\eta}=\iota(\eta) d \iota(\eta) \hat{\eta}$ for all $\eta$ and $\hat{\eta}$.

Let $p>2$ and denote by $\operatorname{Diff}_{0}^{2, p}(\Sigma)$ and $\mathcal{J}^{1, p}(\Sigma)$ the appropriate Sobolev completions. Consider the map

$$
\operatorname{Diff}_{0}^{2, p}(\Sigma) \times B \rightarrow \mathcal{J}^{1, p}(\Sigma):(\phi, \eta) \mapsto \phi^{*} \iota(\eta)
$$

This is a smooth map between Banach manifolds and, by construction, its differential at (id, 0 ) is bijective. Hence, by the inverse function theorem, it restricts to a diffeomorphism from an open neighborhood of (id, 0) in $\operatorname{Diff}_{0}^{2, p}(\Sigma) \times B$ to an open neighborhood of $j_{0}$ in $\mathcal{J}^{1, p}(\Sigma)$. The restriction of this diffeomorphism to the space of smooth pairs in $\operatorname{Diff}_{0}(\Sigma) \times B$ is a diffeomorphism onto an open neighborhood of $j_{0}$ in $\mathcal{J}(\Sigma)$. To see this, note that every element of $\operatorname{Diff}_{0}^{2, p}(\Sigma)$ is a $C^{1}$ diffeomorphism and that every $C^{1}$ diffeomorphism of $\Sigma$ that intertwines two smooth complex structures is necessarily smooth. Shrink $B$ so that $\{\mathrm{id}\} \times B$ is a subset of the neighborhood just constructed. The action of $\operatorname{Diff}_{0}(\Sigma)$ on $\mathcal{J}(\Sigma)$ is free and Lemma 7.5 below asserts that it is proper. Hence, by a standard argument, we may shrink $B$ further so that the local diffeomorphism

$$
\operatorname{Diff}_{0} \times B \rightarrow \mathcal{J}(\Sigma):(\phi, \eta) \mapsto \phi^{*} \iota(\eta)
$$

is injective; it is the required diffeomorphism onto an open neighborhood of the orbit of $j_{0}$.

Lemma 7.5. Let $\Sigma$ be a surface and $j_{k}, j_{k}^{\prime} \in \mathcal{J}(\Sigma)$ and $\phi_{k} \in \operatorname{Diff}(\Sigma)$ be sequences such that $j_{k}^{\prime}$ converges to $j^{\prime} \in \mathcal{J}(\Sigma)$ and $j_{k}=\phi_{k}^{*} j_{k}^{\prime}$ converges to $j \in \mathcal{J}(\Sigma)$. Then $\phi_{k}$ has a subsequence which converges in $\operatorname{Diff}(\Sigma)$.

Proof. Fix an embedded closed disk $D \subset \Sigma$ and two points $z_{0} \in \operatorname{int}(D), z_{1} \in \partial D$. Let $\mathbb{D} \subset \mathbb{C}$ denote the closed unit disk. By the Riemann mapping theorem, there is a unique diffeomorphism $u_{k}: \mathbb{D} \rightarrow D$ such that

$$
u_{k}^{*} j_{k}=i, \quad u_{k}(0)=z_{0}, \quad u_{k}(1)=z_{1}
$$

The standard bubbling and elliptic bootstrapping arguments for $J$-holomorphic curves (see [16, Appendix B]) show that $u_{k}$ converges in the $C^{\infty}$ topology. The same arguments
show that the sequence $u_{k}^{\prime}:=\phi_{k} \circ u_{k}$ of $j_{k}^{\prime}$-holomorphic disks has a subsequence which converges on every compact subset of the interior of $\mathbb{D}$. Thus we have proved that the restriction of $\phi_{k}$ to any embedded disk in $\Sigma$ has a convergent subsequence. Hence $\phi_{k}$ has a convergent subsequence. The limit $\phi$ satisfies $\phi^{*} j^{\prime}=j$ and has degree one. Hence $\phi$ is a diffeomorphism.

## 8. Teichmüller space

The space $\mathcal{T}_{g}$
In this section we prove Theorems 5.3-5.6for $g>1$ in the case of surfaces without nodes or marked points.
8.1. Let $A$ be a complex manifold and $\Sigma$ be a surface. We denote the complex structure on $A$ by $\sqrt{-1}$. An almost complex structure on $A \times \Sigma$ with respect to which the projection $A \times \Sigma \rightarrow A$ is holomorphic has the form

$$
J=\left(\begin{array}{cc}
\sqrt{-1} & 0  \tag{6}\\
\alpha & j
\end{array}\right),
$$

where $j: A \rightarrow \mathcal{J}(\Sigma)$ is a smooth function with values in the space of (almost) complex structures on $\Sigma$ and $\alpha \in \Omega^{1}(A, \operatorname{Vect}(\Sigma))$ is a smooth 1 -form on $A$ with values in the space of vector fields on $\Sigma$ such that

$$
\begin{equation*}
\alpha(a, \sqrt{-1} \hat{a})+j(a) \alpha(a, \hat{a})=0 \tag{7}
\end{equation*}
$$

for all $a \in A$ and $\hat{a} \in T_{a} A$. This means that the 1 -form $\alpha$ is complex anti-linear with respect to the complex structure on the vector bundle $A \times \operatorname{Vect}(\Sigma) \rightarrow A$ determined by $j$. From an abstract point of view it is useful to think of $\alpha$ as a connection on the (trivial) principal bundle $A \times \operatorname{Diff}(\Sigma)$ and of $j: A \rightarrow \mathcal{J}(\Sigma)$ as a section of the associated fiber bundle $A \times \mathcal{J}(\Sigma)$. This section is holomorphic with respect to the Cauchy-Riemann operator associated to the connection $\alpha$ if and only if

$$
\begin{equation*}
d j(a) \hat{a}+j(a) d j(a) \sqrt{-1} \hat{a}+j(a) \mathcal{L}_{\alpha(a, \hat{a})} j(a)=0 \tag{8}
\end{equation*}
$$

for all $a \in A$ and $\hat{a} \in T_{a} A$. (For a finite-dimensional analogue see for example [2].)
Lemma 8.2. $J$ is integrable if and only if $j$ and $\alpha$ satisfy (8).
Proof. It suffices to consider the case $m=1$, so $A \subset \mathbb{C}$ with coordinate $s+i t$. Then the complex structure $J$ on $A \times \Sigma$ has the form

$$
J=\left(\begin{array}{ccc}
0 & -1 & 0  \tag{9}\\
1 & 0 & 0 \\
-j \xi & -\xi & j
\end{array}\right),
$$

where $A \rightarrow \mathcal{J}(\Sigma): s+i t \mapsto j_{s, t}$ and $A \rightarrow \operatorname{Vect}(\Sigma): s+i t \mapsto \xi_{s, t}$ are smooth maps. The equation (8) has the form

$$
\begin{equation*}
\partial_{s} j+j \partial_{t} j+\mathcal{L}_{\xi} j=0 \tag{10}
\end{equation*}
$$

To see that this is equivalent to integrability of $J$ evaluate the Nijenhuis tensor $N_{J}(X, Y)$ $:=[J X, J Y]-J[X, J Y]-J[J X, Y]-[X, Y]$ on a pair of vectors of the form $X=$ $(1,0,0), Y=(0,0, \hat{z})$. The condition $N_{J}(X, Y)=0$ for all such vectors is equivalent to 10) and it is easy to see that $N_{J}=0$ if and only if $N_{J}((1,0,0),(0,0, \hat{z}))=0$ for all $\hat{z} \in T \Sigma$. The latter assertion uses the facts that $N_{J}$ is bilinear, $N_{J}(X, Y)=-N_{J}(Y, X)=$ $J N_{J}(J X, Y)$, and every complex structure on a 2-manifold is integrable. This proves the lemma.

Let $A$ be a complex manifold and $\iota: A \rightarrow \mathcal{J}(\Sigma)$ be a holomorphic map. Consider the fibration

$$
\pi_{\imath}: P_{l}:=A \times \Sigma \rightarrow A
$$

with almost complex structure

$$
J_{l}(a, z):=\left(\begin{array}{cc}
\sqrt{-1} & 0  \tag{11}\\
0 & \iota(a)(z)
\end{array}\right)
$$

By Lemma 8.2 the almost complex structure $J_{l}$ on $P_{l}$ is integrable.
Lemma 8.3. Let $a \in A$. Then the pair $\left(\pi_{l}, a\right)$ is an infinitesimally universal unfolding if and only if the restriction of $\iota$ to a sufficiently small neighborhood of a is a local slice as in Theorem 7.4

Proof. Let $u: \Sigma \rightarrow P_{a}$ be the diffeomorphism $u(z):=(a, z)$ and define $j:=\iota(a)$. Then the linearized operator $D_{u, a}$ (at the pair $(u, a)$ for the equation $\bar{\partial}_{j} u=0$ with $\left.j=\iota(a)\right)$ has domain $\mathcal{X}_{u, a}=\Omega^{0}(\Sigma, T \Sigma) \times T_{a} A$, target space $\mathcal{Y}_{u}=\Omega_{j}^{0,1}(\Sigma, T \Sigma)$ and is given by

$$
D_{u, a}(\hat{u}, \hat{a})=\bar{\partial}_{j} \hat{u}-\frac{1}{2} j d \iota(a) \hat{a} .
$$

(See the formula in [16, p. 176] with $v=$ id.) This operator is bijective if and only if $d \iota(a)$ is injective and its image in $T_{j} \mathcal{J}=\Omega_{j}^{0,1}(\Sigma, T \Sigma)$ is a complement of im $\bar{\partial}_{j}=$ $T_{j}\left(\operatorname{Diff}_{0}(\Sigma)^{*} j\right.$ ) (see the proof of Theorem7.4). This proves the lemma.

Theorem 8.4. Theorems 5.35 .6 hold for Riemann surfaces of genus $g>1$ without nodes and marked points.

Proof. Let $\Sigma$ be a surface of genus $g$. Abbreviate

$$
\mathcal{D}_{0}:=\operatorname{Diff}_{0}(\Sigma), \quad \mathcal{J}:=\mathcal{J}(\Sigma), \quad \mathcal{T}:=\mathcal{T}(\Sigma):=\mathcal{J}(\Sigma) / \operatorname{Diff}_{0}(\Sigma)
$$

Thus $\mathcal{T}_{g}:=\mathcal{T}$ is Teichmüller space. Consider the principal fiber bundle

$$
\mathcal{D}_{0} \rightarrow \mathcal{J} \rightarrow \mathcal{T}
$$

The associated fiber bundle

$$
\pi_{\mathcal{T}}: \mathcal{Q}:=\mathcal{J} \times \times_{\mathcal{D}_{0}} \Sigma \rightarrow \mathcal{T}
$$

has fibers isomorphic to $\Sigma$.

Step 1. $\mathcal{Q}$ and $\mathcal{T}$ are complex manifolds and $\pi_{\mathcal{T}}$ is a proper holomorphic submersion.
By Lemma 8.2 with $A=\mathcal{J}$ and the map $A \rightarrow \mathcal{J}$ equal to the identity, the space $\mathcal{J} \times \Sigma$ is a complex manifold. Since $\mathcal{D}_{0}$ acts by holomorphic diffeomorphisms, so is the (finitedimensional) quotient $\mathcal{Q}$.

Step 2. The projection $\pi_{\mathcal{T}}$ is an infinitesimally universal unfolding of each of its fibers.
Choose $\left[j_{0}\right] \in \mathcal{T}$. Let $B$ be an open neighborhood of 0 in $\mathbb{C}^{3 g-3}$ and $\iota: B \rightarrow \mathcal{J}$ be a local holomorphic slice such that $\iota(0)=j_{0}$ (see [20] or Section 7]. Then the projection $Q_{\iota} \rightarrow B$ is a local coordinate chart on $\mathcal{Q} \rightarrow \mathcal{T}$. Hence Step 2 follows from Lemma 8.3

Step 3. Every pseudomorphism from $\left(\pi_{A}, a_{0}\right)$ to $\left(\pi_{\mathcal{T}},\left[j_{0}\right]\right)$ is a morphism.
Let $(\phi, \Phi)$ be a pseudomorphism from $\left(\pi_{A}: P \rightarrow A, a_{0}\right)$ to $\left(\pi_{\mathcal{T}},\left[j_{0}\right]\right)$ and $\iota: B \rightarrow \mathcal{J}$ be as in the proof of Step 2. Define $(\psi, \Psi)$ to be the composition of $(\phi, \Phi)$ with the obvious morphism from $\left(\pi_{\mathcal{T}},\left[j_{0}\right]\right)$ to $\left(Q_{\iota}, 0\right)$. Using the maps $\Psi_{a}: P_{a} \rightarrow \Sigma$ given by $\Psi(p)=:\left(\psi(a), \Psi_{a}(p)\right)$ for $p \in P_{a}$ we construct a trivialization

$$
\tau: A \times \Sigma \rightarrow P, \quad \tau(a, z):=\tau_{a}(z):=\Psi_{a}^{-1}(z) .
$$

Then the pullback of the complex structure on $P$ under $\tau$ has the form

$$
J(a, z):=\left(\begin{array}{cc}
\sqrt{-1} & 0 \\
\alpha & j(a)(z)
\end{array}\right)
$$

where $j:=\iota \circ \psi: A \rightarrow \mathcal{J}$ and $\alpha \in \Omega_{j}^{0,1}(A, \operatorname{Vect}(\Sigma))$. Since $J$ is integrable it follows from Lemma 8.2 that $j$ and $\alpha$ satisfy (8). Since the local slice is holomorphic the term $\operatorname{dj}(a) \hat{a}+j(a) d j(a) \sqrt{-1} \hat{a}$ is tangent to the slice while the last summand $j(a) \mathcal{L}_{\alpha(a, \hat{a})} j(a)=-\mathcal{L}_{\alpha(a, \sqrt{-1} \hat{a})} j(a)$ is tangent to the orbit of $j(a)$ under $\mathcal{D}_{0}$. It follows that both terms vanish for all $a \in A$ and $\hat{a} \in T_{a} A$. Hence $\alpha=0$ and the map $j: A \rightarrow \mathcal{J}$ is holomorphic. Therefore $\psi: A \rightarrow B$ is holomorphic and hence so is $\Psi$.

Step 4. $\pi_{\mathcal{T}}$ is a universal unfolding of each of its fibers.
Choose an unfolding $\left(\pi_{A}: P \rightarrow A, a_{0}\right)$ and a holomorphic diffeomorphism $u_{0}:\left(\Sigma, j_{0}\right)$ $\rightarrow P_{a_{0}}$. Then $u_{0}^{-1}$ is a fiber isomorphism from $P_{a_{0}}$ to $\mathcal{Q}_{\left[j_{0}\right]}$. Trivialize $P$ by a map $\tau: A \times \Sigma \rightarrow P$ such that $\tau_{a_{0}}=u_{0}$. Define $j: A \rightarrow \mathcal{J}$ so that $j(a)$ is the pullback of the complex structure on $P_{a}$ under $\tau_{a}$. Then $j\left(a_{0}\right)=j_{0}$. Define $\phi: A \rightarrow \mathcal{T}$ and $\Phi: P \rightarrow \mathcal{Q}$ by

$$
\phi(a):=[j(a)], \quad \Phi(p):=[j(a), z], \quad p=: \tau(a, z)
$$

for $a \in A$ and $p \in P_{a}$. This is a pseudomorphism and hence, by Step 3, it is a morphism.
To prove uniqueness, choose a local holomorphic slice $\iota: B \rightarrow \mathcal{J}$ such that $\iota(0)=j_{0}$. Choose two morphisms $(\psi, \Psi),(\phi, \Phi):\left(\pi_{A}, a_{0}\right) \rightarrow\left(\pi_{\iota}, 0\right)$ such that $\Phi_{a_{0}}=\Psi_{a_{0}}=$ $u_{0}^{-1}: P_{a_{0}} \rightarrow \Sigma$. If $a$ is near $a_{0}$ then

$$
\Psi_{a} \circ \Phi_{a}^{-1}:(\Sigma, \iota(\phi(a))) \rightarrow(\Sigma, \iota(\psi(a)))
$$

is a diffeomorphism close to the identity and hence isotopic to the identity. Hence by the local slice property $\phi(a)=\psi(a)$ and $\Psi_{a} \circ \Phi_{a}^{-1}=\mathrm{id}$.
Step 5. Let $j_{0}$ be a complex structure on $\Sigma$. Every infinitesimally universal unfolding $\left(\pi_{B}: Q \rightarrow B, b_{0}\right)$ of $\left(\Sigma_{0}, j_{0}\right)$ is isomorphic to $\left(\pi_{\mathcal{T}},\left[j_{0}\right]\right)$.
As in Step 3 we may assume that $Q=B \times \Sigma$ with complex structure

$$
J(b, z):=\left(\begin{array}{cc}
\sqrt{-1} & 0 \\
0 & \iota(b)(z)
\end{array}\right)
$$

where $\iota: B \rightarrow \mathcal{J}$ is holomorphic and $\iota\left(b_{0}\right)=j_{0}$. By Lemma 8.2 this almost complex structure is integrable. Since ( $\pi_{B}: Q \rightarrow B, b_{0}$ ) is infinitesimally universal, it follows from Lemma 8.3 that the restriction of $\iota$ to a neighborhood of $b_{0}$ is a local slice. Hence $\left(\pi_{B}, b_{0}\right)$ is isomorphic to $\left(\pi_{\mathcal{T}},\left[j_{0}\right]\right)$ by the local slice property.
Remark 8.5. The universal unfolding $\pi_{\mathcal{T}}: \mathcal{Q} \rightarrow \mathcal{T}$ of Theorem 8.4 determines an etale $\operatorname{groupoid}(B, \Gamma)$ with $B:=\mathcal{T}=\mathcal{J}(\Sigma) / \operatorname{Diff}_{0}(\Sigma)$ and

$$
\Gamma:=\left\{\left[j, \phi, j^{\prime}\right]: j, j^{\prime} \in \mathcal{J}(\Sigma), \phi \in \operatorname{Diff}(\Sigma), j=\phi^{*} j^{\prime}\right\}
$$

Here $\left[j, \phi, j^{\prime}\right]$ denotes the equivalence class under the diagonal action of $\operatorname{Diff}_{0}(\Sigma)$ by $\psi^{*}\left(j, \phi, j^{\prime}\right):=\left(\psi^{*} j, \psi^{-1} \circ \phi \circ \psi, \psi^{*} j^{\prime}\right)$. By Lemma 7.5 this etale groupoid is proper.

The space $\mathcal{T}_{g, n}$
In this section we prove Theorems $5.3-5.6$ for all stable marked Riemann surfaces without nodes. Let $\left(\Sigma, s_{*}, j_{0}\right)$ be a stable marked Riemann surface of type $(g, n)$ without nodes. We will construct an infinitesimally universal unfolding ( $\pi_{B}, S_{*}, b_{0}$ ) of ( $\Sigma, j_{0}, s_{*}$ ), prove that it is universal, and prove that every infinitesimally universal unfolding of $\left(\Sigma, s_{*}, j_{0}\right)$ is isomorphic to the one we have constructed.
8.6. Let $n$ and $g$ be nonnegative integers such that $n>2-2 g$ and let $\Sigma$ be a surface of genus $g$. Abbreviate

$$
\mathcal{G}:=\operatorname{Diff}_{0}(\Sigma), \quad \mathcal{P}:=\mathcal{J}(\Sigma) \times\left(\Sigma^{n} \backslash \Delta\right), \quad \mathcal{B}:=\mathcal{P} / \mathcal{G}
$$

where $\Delta \subset \Sigma^{n}$ denotes the fat diagonal, i.e. the set of all $n$-tuples of points in $\Sigma^{n}$ where at least two components are equal. Thus $\mathcal{B}=\mathcal{T}_{g, n}$ is the Teichmüller space of Riemann surfaces of genus $g$ with $n$ distinct marked points. Consider the principal fiber bundle

$$
\mathcal{G} \rightarrow \mathcal{P} \rightarrow \mathcal{B}
$$

The associated fiber bundle

$$
\pi_{\mathcal{B}}: \mathcal{Q}:=\mathcal{P} \times_{\mathcal{G}} \Sigma \rightarrow \mathcal{B}
$$

has fibers isomorphic to $\Sigma$ and is equipped with $n$ disjoint sections

$$
\mathcal{S}_{i}:=\left\{\left[j, s_{1}, \ldots, s_{n}, z\right] \in \mathcal{Q}: z=s_{i}\right\}, \quad i=1, \ldots, n
$$

It is commonly called the universal curve of genus $g$ with $n$ marked points.
8.7. Let $\left(j_{0}, r_{*}\right) \in \mathcal{P}, A$ be a complex manifold, $a_{0} \in A$, and let $\iota=\left(\iota_{0}, \iota_{1}, \ldots, \iota_{n}\right)$ : $A \rightarrow \mathcal{P}$ be a holomorphic map such that

$$
\begin{equation*}
\iota_{0}\left(a_{0}\right)=j_{0}, \quad \iota_{i}\left(a_{0}\right)=r_{i}, \quad i=1, \ldots, n \tag{12}
\end{equation*}
$$

Define the unfolding ( $\pi_{\iota}: P_{\iota} \rightarrow A, R_{\iota, *}, a_{0}$ ) by

$$
P_{\iota}:=A \times \Sigma, \quad J_{\iota}(a, z):=\left(\begin{array}{cc}
\sqrt{-1} & 0  \tag{13}\\
0 & \iota_{0}(a)(z)
\end{array}\right)
$$

where $\sqrt{-1}$ denotes the complex structure on $A$ and

$$
\begin{equation*}
R_{\iota, i}:=\left\{\left(a, \iota_{i}(a)\right): a \in A\right\}, \quad i=1, \ldots, n \tag{14}
\end{equation*}
$$

Lemma 8.8. The unfolding ( $\pi_{\iota}, R_{\iota, *}, a_{0}$ ) is infinitesimally universal if and only if the restriction of $\iota$ to a sufficiently small neighborhood of $a_{0}$ is a (holomorphic) local slice for the action of $\mathcal{G}$ on $\mathcal{P}$.

Proof. Let $u_{0}:\left(\Sigma, j_{0}\right) \rightarrow A$ be the holomorphic embedding $u_{0}(z):=\left(a_{0}, z\right)$. Then the operator $D_{u_{0}, a_{0}}$ has domain

$$
\mathcal{X}_{0}:=\left\{(\hat{u}, \hat{a}) \in \Omega^{0}(\Sigma, T \Sigma) \times T_{a_{0}} A: \hat{u}\left(r_{i}\right)=d \iota_{i}\left(a_{0}\right) \hat{a}\right\}
$$

target space $\mathcal{Y}_{0}:=\Omega_{j_{0}}^{0,1}(\Sigma, T \Sigma)$, and is given by

$$
D_{u_{0}, a_{0}}(\hat{u}, \hat{a})=\bar{\partial}_{j_{0}} \hat{u}-\frac{1}{2} j_{0} d \iota_{0}\left(a_{0}\right) \hat{a} .
$$

Now the tangent space of the group orbit $\mathcal{G}^{*}\left(j_{0}, r_{*}\right)$ at $\left(j_{0}, r_{*}\right)$ is given by

$$
T_{\left(j_{0}, r_{*}\right)} \mathcal{G}^{*}\left(j_{0}, r_{*}\right)=\left\{\left(2 j_{0} \bar{\partial}_{j_{0}} \xi,-\xi\left(r_{1}\right), \ldots,-\xi\left(r_{n}\right)\right): \xi \in \Omega^{0}(\Sigma, T \Sigma)\right\}
$$

(See the proof of Theorem 7.1 for the formula $\mathcal{L}_{\xi} j_{0}=2 j_{0} \bar{\partial}_{j_{0}} \xi$.) Hence the operator $D_{u_{0}, a_{0}}$ is injective if and only if im $d \iota\left(a_{0}\right) \cap T_{\left(j_{0}, r_{*}\right)} \mathcal{G}^{*}\left(j_{0}, r_{*}\right)=0$ and $d \iota\left(a_{0}\right)$ is injective. It is surjective if and only if $\operatorname{im} d \iota\left(a_{0}\right)+T_{\left(j_{0}, r_{*}\right)} \mathcal{G}^{*}\left(j_{0}, r_{*}\right)=T_{\left(j_{0}, r_{*}\right)} \mathcal{P}$. This proves the lemma.

Theorem 8.9. Theorems 5.3-5.6 hold for marked Riemann surfaces without nodes.
Proof.
Step 1. $\mathcal{Q}$ and $\mathcal{B}$ are complex manifolds, the projection $\pi_{\mathcal{B}}$ is a proper holomorphic submersion, and $\mathcal{S}_{1}, \ldots, \mathcal{S}_{n}$ are complex submanifolds of $\mathcal{Q}$.
Apply Lemma 8.2 to the complex manifold $A=\mathcal{J}=\mathcal{J}(\Sigma)$, replace the fiber $\Sigma$ by $\Sigma^{n} \backslash \Delta$, and replace $\iota$ by the map $\mathcal{J} \rightarrow \mathcal{J}\left(\Sigma^{n} \backslash \Delta\right)$ which assigns to each complex structure $j \in \mathcal{J}(\Sigma)$ the corresponding product structure on $\Sigma^{n} \backslash \Delta$. Then (the proof of) Lemma 8.2 shows that $\mathcal{P}=\mathcal{J} \times\left(\Sigma^{n} \backslash \Delta\right)$ is a complex manifold. The group $\mathcal{G}=\operatorname{Diff}_{0}(\Sigma)$ acts on this space by the holomorphic diffeomorphisms

$$
\left(j, s_{1}, \ldots, s_{n}\right) \mapsto\left(f^{*} j, f^{-1}\left(s_{1}\right), \ldots, f^{-1}\left(s_{n}\right)\right)
$$

for $f \in \mathcal{G}$. The action is free and admits holomorphic local slices for all $g$ and $n$. It follows that the quotient $\mathcal{B}=\mathcal{P} / \mathcal{G}$ is a complex manifold. The same argument shows that the total space $\mathcal{Q}$ is a complex manifold and that the projection $\pi_{\mathcal{B}}: \mathcal{Q} \rightarrow \mathcal{B}$ is holomorphic. That it is a proper submersion is immediate from the definitions.

Here are more details on the holomorphic local slices for the action of $\mathcal{G}$ on $\mathcal{P}$. In the case $g>1$ we will find a holomorphic local slice $\iota: B \rightarrow \mathcal{P}$, defined on $B:=$ $B_{0} \times \operatorname{int}(\mathbb{D})^{n}$, which has the form

$$
\iota\left(b_{0}, b_{1}, \ldots, b_{n}\right)=\left(\iota_{0}\left(b_{0}\right), \iota_{1}\left(b_{0}, b_{1}\right), \ldots, \iota_{n}\left(b_{0}, b_{n}\right)\right)
$$

Here $\iota_{0}: B_{0} \rightarrow \mathcal{J}$ is a holomorphic local slice as in Theorem 7.4. For $i=1, \ldots, n$, the map $\left(b_{0}, b_{i}\right) \mapsto\left(b_{0}, \iota_{i}\left(b_{0}, b_{i}\right)\right)$ is holomorphic with respect to the complex structure $J_{\iota_{0}}$ on $Q_{0}:=B_{0} \times \Sigma$ defined by (13) and restricts to a holomorphic embedding from $b_{0} \times \operatorname{int}(\mathbb{D})$ to $(\Sigma, j)$ with $j=\iota_{0}\left(b_{0}\right)$. That such maps $\iota_{i}$ exist and can be chosen with disjoint images follows from Lemma 7.2 .

In the case $g=1$ and $n \geq 1$ with $\Sigma=\mathbb{T}^{2}:=\mathbb{R}^{2} / \mathbb{Z}^{2}$ an example of a holomorphic local slice is the map $\iota: B=B_{0} \times B_{1} \times \cdots \times B_{n-1} \rightarrow \mathcal{P}$ given by

$$
\iota\left(\lambda_{0}, b_{1}, \ldots, b_{n-1}\right):=\left(j\left(\lambda_{0}\right), f_{\lambda_{0}}^{-1}\left(b_{1}\right), \ldots, f_{\lambda_{0}}^{-1}\left(b_{n-1}\right), f_{\lambda_{0}}^{-1}\left(s_{n}\right)\right)
$$

where $B_{0} \subset \mathbb{H}$ and $B_{i} \subset \mathbb{C}$ are open sets such that closures of the $n-1$ sets $B_{i}+$ $\mathbb{Z}+\lambda_{0} \mathbb{Z} \subset T_{\lambda_{0}}:=\mathbb{C} / \mathbb{Z}+\lambda_{0} \mathbb{Z}$ are pairwise disjoint, none of these sets contains the point $s_{n}+\mathbb{Z}+\lambda_{0} \mathbb{Z}$, the complex structure $j\left(\lambda_{0}\right) \in \mathcal{J}\left(\mathbb{T}^{2}\right)$ is defined by 5 , and the isomorphism $f_{\lambda_{0}}:\left(\mathbb{T}^{2}, j\left(\lambda_{0}\right)\right) \rightarrow T_{\lambda_{0}}$ is defined by $f_{\lambda_{0}}(x, y):=x+\lambda_{0} y$. That any such map is a holomorphic local slice for the action of $\mathcal{G}=\operatorname{Diff}_{0}\left(\mathbb{T}^{2}\right)$ follows from Theorem 7.3

In the case $g=0$ and $n \geq 3$ with $\Sigma=S^{2}$, an example of a holomorphic local slice is the map $\iota: B=\operatorname{int}(\mathbb{D})^{n-3} \rightarrow \mathcal{P}$ given by

$$
\iota\left(b_{1}, \ldots, b_{n-s}\right):=\left(j_{0}, \iota_{1}\left(b_{1}\right), \ldots, \iota_{n-3}\left(b_{n-3}\right), s_{n-2}, s_{n-1}, s_{n}\right)
$$

where $s_{n-2}, s_{n-1}, s_{n}$ are distinct points in $S^{2}, j_{0} \in \mathcal{J}\left(S^{2}\right)$ denotes the standard complex structure, and the $\iota_{i}: \operatorname{int}(\mathbb{D}) \rightarrow S^{2}$ are holomorphic embeddings for $1 \leq i \leq n-3$ such that the closures of their images are pairwise disjoint and do not contain the points $s_{n-2}, s_{n-1}, s_{n}$. That any such map is a holomorphic local slice for the action of $\mathcal{G}=$ $\operatorname{Diff}_{0}\left(S^{2}\right)$ follows from Theorem 7.1.

Thus we have constructed holomorphic local slices for the action of $\mathcal{G}=\operatorname{Diff}_{0}(\Sigma)$ on $\mathcal{P}=\mathcal{J}(\Sigma) \times\left(\Sigma^{n} \backslash \Delta\right)$ in all cases. Holomorphic slices for the action of $\mathcal{G}$ on $\mathcal{P} \times \Sigma$ can be constructed in a similar fashion. It then follows from the symmetry of the construction under permutations of the components in $\Sigma$ that the sections $\mathcal{S}_{i}$ are complex submanifolds of $\mathcal{Q}$. This proves Step 1.

Step 2. The pair $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*}\right)$ is an infinitesimally universal unfolding of each of its fibers.
Choose $\left[j_{0}, s_{*}\right] \in \mathcal{B}$. Let $B$ be an open neighborhood of $b_{0}=0$ in $\mathbb{C}^{3 g-3+n}$ and $\iota=$ $\left(\iota_{0}, \iota_{1}, \ldots, \iota_{n}\right): B \rightarrow \mathcal{P}$ be a local holomorphic slice satisfying (12). Then the unfolding
$\left(\pi_{\iota}: Q_{\iota} \rightarrow B, S_{\iota, *}, b_{0}\right)$ defined as in 13) and 14 is isomorphic to $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*},\left[j_{0}, s_{*}\right]\right)$. Hence Step 2 follows from Lemma 8.8 .

Step 3. Every pseudomorphism from $\left(\pi_{A}, R_{*}, a_{0}\right)$ to $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*},\left[j_{0}, s_{*}\right]\right)$ is a morphism.
Let $(\phi, \Phi)$ be a pseudomorphism from ( $\left.\pi_{A}: P \rightarrow A, R_{*}, a_{0}\right)$ to $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*},\left[j_{0}, s_{*}\right]\right)$ and $\iota=\left(\iota_{0}, \iota_{1}, \ldots, \iota_{n}\right): B \rightarrow \mathcal{P}$ be as in the proof of Step 2 . Define $(\psi, \Psi)$ to be the composition of $(\phi, \Phi)$ with the obvious morphism from $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*},\left[j_{0}, s_{*}\right]\right)$ to the unfolding $\left(Q_{l}, S_{l, *}, b_{0}\right)$, defined as in (13) and (14). Using the maps $\Psi_{a}: P_{a} \rightarrow \Sigma$ given by $\Psi(p)=:\left(\psi(a), \Psi_{a}(p)\right)$ for $p \in P_{a}$ we construct a trivialization

$$
\tau: A \times \Sigma \rightarrow P, \quad \tau(a, z):=\tau_{a}(z):=\Psi_{a}^{-1}(z) .
$$

Then the pullback of the section $R_{i}$ is given by

$$
\tau^{-1}\left(R_{i}\right)=\left\{\left(a, \sigma_{i}(a)\right): a \in A\right\}, \quad \sigma_{i}:=\iota_{i} \circ \psi: A \rightarrow \Sigma,
$$

and the pullback of the complex structure on $P$ under $\tau$ has the form

$$
J(a, z):=\left(\begin{array}{cc}
\sqrt{-1} & 0 \\
\alpha & j(a)(z)
\end{array}\right)
$$

where $j:=\iota_{0} \circ \psi: A \rightarrow \mathcal{J}$ and $\alpha \in \Omega_{j}^{0,1}(A, \operatorname{Vect}(\Sigma))$. Since $J$ is integrable it follows from Lemma 8.2 that $j$ and $\alpha$ satisfy

$$
d j(a) \hat{a}+j(a) d j(a) \sqrt{-1} \hat{a}-\mathcal{L}_{\alpha(a, \sqrt{-1} \hat{a})} j(a)=0 .
$$

Since $\tau^{-1}\left(R_{i}\right)$ is a complex submanifold of $A \times \Sigma$, we have

$$
\begin{equation*}
d \sigma_{i}(a) \hat{a}+j(a) d \sigma_{i}(a) \sqrt{-1} \hat{a}+\alpha(a, \sqrt{-1} \hat{a})\left(\sigma_{i}(a)\right)=0 \tag{15}
\end{equation*}
$$

for $i=1, \ldots, n$. Since $\iota$ is a local holomorphic slice these two equations together imply that

$$
d j(a) \hat{a}+j(a) d j(a) \sqrt{-1} \hat{a}=0, \quad d \sigma_{i}(a) \hat{a}+j(a) d \sigma_{i}(a) \sqrt{-1} \hat{a}=0,
$$

and $\mathcal{L}_{\alpha(a, \sqrt{-1} \hat{a})} j(a)=0$ and $\alpha(a, \sqrt{-1} \hat{a})\left(\sigma_{i}(a)\right)=0$ for all $\hat{a} \in T_{a} A$. Since $n>2-2 g$ it follows that $\alpha \equiv 0$. Moreover, the map $\left(j, \sigma_{1}, \ldots, \sigma_{n}\right)=\iota \psi: A \rightarrow \mathcal{P}$ is holomorphic. Since $\iota$ is a holomorphic local slice, this implies that $\psi$, and hence also $\Psi$, is holomorphic.

Step 4. The pair $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*}\right)$ is a universal unfolding of each of its fibers.
Choose $\left[j_{0}, s_{*}\right] \in \mathcal{B}$ and let $\left(\pi_{A}: P \rightarrow A, a_{0}\right)$ admit an isomorphism $u_{0}:\left(\Sigma, j_{0}\right) \rightarrow P_{a_{0}}$ such that $u_{0}\left(s_{i}\right):=P_{a_{0}} \cap R_{i}$. Then $u_{0}^{-1}$ is a fiber isomorphism from $P_{a_{0}}$ to $\mathcal{Q}_{\left[j_{0}, s_{*}\right]}$. Trivialize $P$ by a map $\tau: A \times \Sigma \rightarrow P$ such that $\tau_{a_{0}}=u_{0}$. Define $j: A \rightarrow \mathcal{J}$ and $\sigma_{i}: A \rightarrow \Sigma$ so that $j(a)$ is the pullback of the complex structure on $P_{a}$ under $\tau_{a}$ and $\tau^{-1}\left(R_{i}\right)=\left\{\left(a, \sigma_{i}(a)\right): a \in A\right\}$. Then $j\left(a_{0}\right)=j_{0}$ and $\sigma_{i}\left(a_{0}\right)=s_{i}$. Define $\phi: A \rightarrow \mathcal{B}$ and $\Phi: P \rightarrow \mathcal{Q}$ by

$$
\phi(a):=\left[j(a), \sigma_{*}(a)\right], \quad \Phi(p):=\left[j(a), \sigma_{*}(a), z\right], \quad p=: \tau(a, z)
$$

for $a \in A$ and $p \in P_{a}$. This is a pseudomorphism and hence, by Step 3, it is a morphism. To prove uniqueness, choose a local holomorphic slice $\iota=\left(\iota_{0}, \iota_{1}, \ldots, \iota_{n}\right): B \rightarrow \mathcal{P}$ such that $\iota\left(b_{0}\right)=\left(j_{0}, s_{1}, \ldots, s_{n}\right)$. Choose two morphisms

$$
(\psi, \Psi),(\phi, \Phi):\left(\pi_{A}, R_{*}, a_{0}\right) \rightarrow\left(\pi_{\iota}, S_{l, *}, b_{0}\right)
$$

such that $\Phi_{a_{0}}=\Psi_{a_{0}}=u_{0}^{-1}: P_{a_{0}} \rightarrow \Sigma$. If $a$ is near $a_{0}$ then

$$
\Psi_{a} \circ \Phi_{a}^{-1}:\left(\Sigma, \iota_{0}(\phi(a))\right) \rightarrow\left(\Sigma, \iota_{0}(\psi(a))\right)
$$

is a diffeomorphism isotopic to the identity that sends $\iota_{i}(\phi(a))$ to $\iota_{i}(\psi(a))$ for $i=$ $1, \ldots, n$. Hence by the local slice property $\phi(a)=\psi(a)$ and $\Phi_{a}=\Psi_{a}$.

Step 5. Let $j_{0}$ be a complex structure on $\Sigma$ and $s_{1}, \ldots, s_{n}$ be distinct marked points on $\Sigma$. Every infinitesimally universal unfolding $\left(\pi_{B}: Q \rightarrow B, S_{*}, b_{0}\right)$ of $\left(\Sigma_{0}, s_{*}, j_{0}\right)$ is isomorphic to $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*},\left[j_{0}, s_{*}\right]\right)$.

As in Step 3 we may assume that $Q=B \times \Sigma$ with complex structure

$$
J(b, z):=\left(\begin{array}{cc}
\sqrt{-1} & 0 \\
0 & \iota_{0}(b)(z)
\end{array}\right)
$$

and $S_{i}=\left\{\left(b, \iota_{i}(b)\right): b \in B\right\}$ where $\iota=\left(\iota_{0}, \iota_{1}, \ldots, \iota_{n}\right): B \rightarrow \mathcal{P}$ is holomorphic and $\iota\left(b_{0}\right)=\left(j_{0}, s_{1}, \ldots, s_{n}\right)$. By Lemma 8.2 the almost complex structure $J$ is integrable. Since ( $\pi_{B}: Q \rightarrow B, S_{*}, b_{0}$ ) is infinitesimally universal, the restriction of $\iota$ to a neighborhood of $b_{0}$ is a local slice by Lemma 8.8. Hence ( $\pi_{B}, S_{*}, b_{0}$ ) is isomorphic to $\left(\pi_{\mathcal{B}}, \mathcal{S}_{*},\left[j_{0}, s_{0}\right]\right)$ by the local slice property.

Remark 8.10. The etale groupoid associated to the universal marked curve of 8.6 is proper as in Remark 8.5

## 9. Nonlinear Hardy spaces

In this section we characterize infinitesimally universal unfoldings in terms of certain "nonlinear Hardy spaces" associated to a desingularization. The idea is to decompose a Riemann surface $\Sigma$ as a union of submanifolds $\Omega$ and $\Delta$, intersecting in their common boundary, and to identify holomorphic maps on $\Sigma$ with pairs of holomorphic maps defined on $\Omega$ and $\Delta$ that agree on that common boundary.
9.1. Throughout this section we assume that

$$
\left(\pi_{B}: Q \rightarrow B, S_{*}, b_{0}\right)
$$

is a nodal unfolding of a marked nodal Riemann surface $\left(\Sigma, s_{*}, v, j\right)$ and that

$$
w_{0}: \Sigma \rightarrow Q_{b_{0}}
$$

is a desingularization. Let $C_{B} \subset Q$ denote the set of critical points of $\pi_{B}$. Let $U$ be a neighborhood of $C_{B}$ equipped with nodal coordinates. This means

$$
U=U_{1} \cup \cdots \cup U_{k}
$$

where the sets $U_{i}$ have pairwise disjoint closures, each $U_{i}$ is a connected neighborhood of one of the components of $C_{B}$, and for $i=1, \ldots, k$ there is a holomorphic coordinate system

$$
\left(\zeta_{i}, \tau_{i}\right): B \rightarrow \mathbb{C} \times \mathbb{C}^{d-1}, \quad d:=\operatorname{dim}_{\mathbb{C}}(B)
$$

and holomorphic functions $\xi_{i}, \eta_{i}: U_{i} \rightarrow \mathbb{C}$ such that

$$
\left(\xi_{i}, \eta_{i}, \tau_{i} \circ \pi_{B}\right): U_{i} \rightarrow \mathbb{C} \times \mathbb{C} \times \mathbb{C}^{d-1}
$$

is a holomorphic coordinate system and $\xi_{i} \eta_{i}=\zeta_{i} \circ \pi_{B}$. Assume that $\bar{U} \cap S_{*}=\emptyset$. Let $V \subset Q$ be an open set such that

$$
Q=U \cup V, \quad \bar{V} \cap C_{B}=\emptyset,
$$

and $U_{i} \cap V$ intersects each fiber $Q_{b}$ in two open annuli with $\left|\xi_{i}\right|>\left|\eta_{i}\right|$ on one component and $\left|\xi_{i}\right|<\left|\eta_{i}\right|$ on the other. Introduce the abbreviations

$$
\begin{gathered}
W:=U \cap V, \quad W_{i}:=U_{i} \cap V, \quad W_{i, 1}:=\left\{\left|\xi_{i}\right|>\left|\eta_{i}\right|\right\}, \quad W_{i, 2}:=\left\{\left|\xi_{i}\right|<\left|\eta_{i}\right|\right\}, \\
U_{b}:=U \cap Q_{b}, \quad V_{b}:=V \cap Q_{b}, \quad W_{b}:=W \cap Q_{b} .
\end{gathered}
$$

9.2. We consider a decomposition

$$
\Sigma=\Omega \cup \Delta, \quad \partial \Omega=\partial \Delta=\Omega \cap \Delta=: \Gamma,
$$

into submanifolds with boundary such that $\Delta$ is a disjoint union

$$
\Delta=\Delta_{1} \cup \cdots \cup \Delta_{k}
$$

where, for each $i$, the set $\Delta_{i}$ is either an embedded closed annulus or the union of two disjoint embedded closed disks centered at two equivalent nodal points, and

$$
w_{0}(\Omega) \subset V, \quad w_{0}\left(\Delta_{i}\right) \subset U_{i}
$$

for $i=1, \ldots, k$. It follows that every pair of equivalent nodal points appears in some $\Delta_{i}$. In case $\Delta_{i}$ is a disjoint union of two disks, say $\Delta_{i}=\Delta_{i, 1} \cup \Delta_{i, 2}$, choose holomorphic diffeomorphisms $x_{i}: \Delta_{i, 1} \rightarrow \mathbb{D}$ and $y_{i}: \Delta_{i, 2} \rightarrow \mathbb{D}$ which send the nodal point to 0 . In case $\Delta_{i}$ is an annulus choose a holomorphic diffeomorphism $x_{i}: \Delta_{i} \rightarrow \mathbb{A}\left(\delta_{i}, 1\right)$ and define $y_{i}: \Delta_{i} \rightarrow \mathbb{A}\left(\delta_{i}, 1\right)$ by $y_{i}=\delta_{i} / x_{i}$. In both cases choose the names so that

$$
w_{0}\left(x_{i}^{-1}\left(S^{1}\right)\right) \subset W_{i, 1}, \quad w_{0}\left(y_{i}^{-1}\left(S^{1}\right)\right) \subset W_{i, 2} .
$$

The curves $\xi_{i} \circ w_{0} \circ x_{i}^{-1}$ and $\eta_{i} \circ w_{0} \circ y_{i}^{-1}$ from $S^{1}$ to $\mathbb{C} \backslash 0$ both have winding number one about the origin.
9.3. Fix an integer $s+1 / 2>1$. Since $\pi_{B} \mid W$ is a submersion, the space $H^{s}\left(\Gamma, W_{b}\right)$ is, for each $b \in B$, a submanifold of the Hilbert manifold of all $H^{s}$ maps from $\Gamma$ to $W$ (see Appendix B). Define an open subset

$$
\mathcal{W}(b) \subset H^{s}\left(\Gamma, W_{b}\right)
$$

by the condition that for $\gamma \in H^{s}\left(\Gamma, W_{b}\right)$ we have $\gamma \in \mathcal{W}(b)$ iff

$$
\gamma\left(x_{i}^{-1}\left(S^{1}\right)\right) \subset W_{i, 1}, \quad \gamma\left(y_{i}^{-1}\left(S^{1}\right)\right) \subset W_{i, 2}
$$

and the curves $\xi_{i} \circ \gamma \circ x_{i}^{-1}$ and $\eta_{i} \circ \gamma \circ y_{i}^{-1}$ from $S^{1}$ to $\mathbb{C} \backslash 0$ both have winding number one about the origin. Introduce sets

$$
\begin{aligned}
\mathcal{Z}(b) & :=\left\{v \in \operatorname{Hol}^{s+1 / 2}\left(\Omega, V_{b}\right): v \mid \Gamma \in \mathcal{W}(b) \text { and } v\left(s_{*} \cap \Omega\right)=S_{*} \cap Q_{b}\right\} \\
\mathcal{N}(b) & :=\left\{u \in \operatorname{Hol}^{s+1 / 2}\left(\Delta, U_{b}\right): u \mid \Gamma \in \mathcal{W}(b) \text { and } u \text { preserves } v\right\}
\end{aligned}
$$

Here we use the notation

$$
\begin{equation*}
\operatorname{Hol}^{s+1 / 2}(X, Y)=\left\{f \in H^{s+1 / 2}(X, Y): d f \circ J_{X}=J_{Y} \circ d f\right\} \tag{16}
\end{equation*}
$$

for a compact Riemann surface $X$ with boundary and an almost complex manifold $Y$. By Theorem B.4 i), restriction to the boundary defines a continuous map $\operatorname{Hol}^{s+1 / 2}(X, Y) \rightarrow$ $H^{s}(\partial X, Y)$. The phrase " $u$ preserves $v$ " means that $\{x, y\} \in v \Rightarrow u(x)=u(y) \in C_{B}$. Define the nonlinear Hardy spaces by

$$
\mathcal{U}(b):=\{u \mid \Gamma: u \in \mathcal{N}(b)\}, \quad \mathcal{V}(b):=\{v \mid \Gamma: v \in \mathcal{Z}(b)\} .
$$

Define

$$
\mathcal{W}_{0}:=\bigsqcup_{b \in B} \mathcal{W}(b), \quad \mathcal{V}_{0}:=\bigsqcup_{b \in B} \mathcal{V}(b), \quad \mathcal{U}_{0}:=\bigsqcup_{b \in B} \mathcal{U}(b)
$$

so that $(\gamma, b) \in \mathcal{W}_{0} \Leftrightarrow \gamma \in \mathcal{W}(b)$, etc. The desingularization $w_{0}: \Sigma \rightarrow Q_{b_{0}}$ determines a point

$$
\begin{equation*}
\left(\gamma_{0}, b_{0}\right) \in \mathcal{U}_{0} \cap \mathcal{V}_{0} \subset \mathcal{W}_{0}, \quad \gamma_{0}:=w_{0} \mid \Gamma \tag{17}
\end{equation*}
$$

Lemma 9.4. For every $(\gamma, b) \in \mathcal{U}_{0} \cap \mathcal{V}_{0}$ there is a unique desingularization $w: \Sigma \rightarrow Q_{b}$ with $w \mid \Gamma=\gamma$.

Proof. Uniqueness is an immediate consequence of unique continuation. To prove existence, let $(\gamma, b) \in \mathcal{U}_{0} \cap \mathcal{V}_{0}$ be given. Then, by definition of $\mathcal{U}_{0}$ and $\mathcal{V}_{0}$, there is a continuous map $w: \Sigma \rightarrow Q_{b}$ which is holomorphic in $\operatorname{int}(\Omega)$ and in $\operatorname{int}(\Delta)$ with $w\left(s_{*}\right)=S_{*} \cap Q_{b}$ and $w\left(z_{0}\right)=w\left(z_{1}\right)$ for every nodal pair $\left\{z_{0}, z_{1}\right\} \in \nu$. The map $w: \Sigma \rightarrow Q$ is of class $H^{s+1 / 2}$ and is therefore holomorphic on all of $\Sigma$. We must prove that if $z_{0} \neq z_{1}$ we have $w\left(z_{0}\right)=w\left(z_{1}\right)$ if and only if $\left\{z_{0}, z_{1}\right\} \in v$. Assume first that there are no nodes, i.e. $Q_{b} \cap C_{B}=\emptyset$. Then $\Delta$ is a union of disjoint annuli and, by the winding number assumption, the restriction of $w$ to $\Delta$ is an embedding into $Q_{b}$ and $w(\Delta) \cup V_{b}=Q_{b}$. Hence there is a point $q \in w(\Delta) \backslash V$. Hence the degree of $w$ at $q$ is one and hence $w: \Sigma \rightarrow Q_{b}$ is a holomorphic diffeomorphism. Now assume
$Q_{b} \cap C_{B} \neq \emptyset$. Then $w^{-1}\left(C_{B}\right)=\bigcup v$, by the winding number assumption, and so the restriction $w: \Sigma \backslash \bigcup v \rightarrow Q_{b} \backslash C_{B}$ is proper. Hence the degree of this restriction is constant on each component of $\Sigma \backslash \bigcup \nu$. Now each component of $\Sigma$ contains a component $\Delta^{\prime}$ of $\Delta$ that is diffeomorphic to a disk. By the winding number assumption, the restriction of $w$ to $\Delta^{\prime}$ is an embedding. Moreover, the images under $w$ of the components of $\Delta \backslash C_{B}$ are disjoint and there is a point $q \in w\left(\Delta^{\prime}\right) \backslash\left(C_{B} \cup V\right)$. Since $w(\Omega) \subset V$, the degree of the restriction $w: \Sigma \backslash \bigcup v \rightarrow Q_{b} \backslash C_{B}$ at any such point $q$ is one. Hence the degree of the restriction is one at every point and hence $w: \Sigma \backslash \bigcup v \rightarrow Q_{b} \backslash C_{B}$ is a holomorphic diffeomorphism. This proves the lemma.

Theorem 9.5. Fix an integer $s+1 / 2>4$. Let $\left(\pi_{B}: Q \rightarrow B, S_{*}, b_{0}\right)$ be a nodal unfolding of a marked nodal Riemann surface $\left(\Sigma, s_{*}, \nu, j\right)$ and $w_{0}: \Sigma \rightarrow Q_{b_{0}}$ be a desingularization as in 9.1 Let $\mathcal{U}_{0}, \mathcal{V}_{0} \subset \mathcal{W}_{0}$ be the subspaces in 9.3 and $\gamma_{0}:=w_{0} \mid \Gamma$ as in 17. Let $D_{w_{0}, b_{0}}$ be the Fredholm operator in Definition 5.2. Then the following holds.
(i) $\mathcal{U}_{0}$ and $\mathcal{V}_{0}$ are complex Hilbert submanifolds of $\mathcal{W}_{0}$.
(ii) The intersection $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0} \cap T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}$ is isomorphic to the kernel of $D_{w_{0}, b_{0}}$.
(iii) The quotient $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0} /\left(T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0}+T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}\right)$ is isomorphic to the cokernel of $D_{w_{0}, b_{0}}$.
(iv) The unfolding $\left(\pi_{B}, S_{*}, b_{0}\right)$ is infinitesimally universal if and only if

$$
T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0}=T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0} \oplus T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}
$$

Proof. We prove that $\mathcal{U}_{0}$ is a complex Hilbert submanifold of $\mathcal{W}_{0}$.
Choose the indexing so that $z_{i}\left(b_{0}\right)=0$ for $i \leq \ell$ and $z_{i}\left(b_{0}\right) \neq 0$ for $i>\ell$. Abbreviate $H^{s}:=H^{s}\left(S^{1}, \mathbb{C}\right)$ for the Sobolev space in B. 1 and consider the map

$$
\mathcal{W}_{0} \rightarrow\left(H^{s}\right)^{2 k} \times B: \gamma \mapsto\left(\alpha_{1}, \beta_{1}, \ldots, \alpha_{k}, \beta_{k}, b\right)
$$

where $\gamma \in \mathcal{W}(b)$ and $\alpha_{i}=\xi_{i} \circ \gamma \circ x_{i}^{-1}$ and $\beta_{i}=\eta_{i} \circ \gamma \circ y_{i}^{-1}$. This maps $\mathcal{W}_{0}$ diffeomorphically onto an open set in a Hilbert space. The map sends $\mathcal{U}_{0} \subset \mathcal{W}_{0}$ to the subset of all tuples $\left(\alpha_{1}, \beta_{1}, \ldots, \alpha_{k}, \beta_{k}, b\right)$ such that all nonpositive coefficients of $\alpha_{i}$ and $\beta_{i}$ vanish for $i \leq \ell$ and

$$
\beta_{i}(y)=\frac{\zeta_{i}(b)}{\alpha_{i}\left(\delta_{i} / y\right)}
$$

for $i>\ell$. Thus the tuple $\left(\alpha_{1}, \beta_{1}, \ldots, \alpha_{\ell}, \beta_{\ell}\right)$ is restricted to a closed subspace of $\left(H^{s}\right)^{2 \ell}$ and, for $i>\ell$, the component $\beta_{i}$ can be expressed as a holomorphic function of $\alpha_{i}$ and $b$. This shows that $\mathcal{U}_{0}$ is a complex Hilbert submanifold of $\mathcal{W}_{0}$.

We will show that the restriction map

$$
\mathcal{Z}_{0}:=\bigsqcup_{b \in B} \mathcal{Z}(b) \rightarrow \mathcal{W}_{0}: v \mapsto v \mid \Gamma
$$

is a holomorphic embedding. Since the image is precisely $\mathcal{V}_{0}$ by definition, this will show that $\mathcal{V}_{0}$ is a complex Hilbert submanifold of $\mathcal{W}_{0}$. Denote by $\mathcal{B}$ the space of all pairs $(v, b)$, where $b \in B$ and $v: \Omega \rightarrow V_{b}$ is an $H^{s+1 / 2}$ map satisfying

$$
v\left(s_{*}\right)=S_{*} \cap Q_{b} .
$$

The space $\mathcal{B}$ is a complex Hilbert manifold whose tangent space at $(v, b)$ is the Sobolev space

$$
T_{v, b} \mathcal{B}=\left\{(\hat{v}, \hat{b}) \in H^{s+1 / 2}\left(\Omega, v^{*} T Q\right) \times T_{b} B: d \pi_{B}(v) \hat{v} \equiv \hat{b}, \hat{v}\left(s_{i}\right) \in T_{v\left(s_{i}\right)} S_{i}\right\}
$$

i.e. $\hat{v}$ is a section of class $H^{s+1 / 2}$ of the pullback tangent bundle $v^{*} T Q$ that projects to a constant tangent vector of $B$ and at the marked points is tangent to $S_{*}$. Consider the complex Hilbert space bundle $\mathcal{E} \rightarrow \mathcal{B}$ whose fiber

$$
\mathcal{E}_{v, b}:=H^{s-1 / 2}\left(\Omega, \Lambda^{0,1} T^{*} \Omega \otimes v^{*} T Q_{b}\right)
$$

over $(v, b) \in \mathcal{B}$ is the Sobolev space of $(0,1)$-forms on $\Omega$ of class $H^{s-1 / 2}$ with values in the vertical pullback tangent bundle $v^{*} T Q_{b}$. The Cauchy-Riemann operator $\bar{\partial}$ is a section of this bundle and its zero set is the space $\mathcal{Z}_{0} \subset \mathcal{B}$ defined above. The vertical derivative of $\bar{\partial}$ at a zero $(v, b)$ is the restriction

$$
D_{v, b}: T_{v, b} \mathcal{B} \rightarrow \mathcal{E}_{v, b}
$$

of the Cauchy-Riemann operator of the holomorphic vector bundle $v^{*} T Q \rightarrow \Omega$ to the subspace $T_{v, b} \mathcal{B} \subset H^{s+1 / 2}\left(\Omega, v^{*} T Q\right)$. This operator is split surjective; a right inverse can be constructed from an appropriate Lagrangian boundary condition (see [16, Appendix C$]$ ). Hence $\mathcal{Z}_{0}$ is a complex submanifold of $\mathcal{B}$.

We show that the restriction map is an injective holomorphic immersion.
By unique continuation at boundary points, the restriction map is injective, i.e. two elements of $\mathrm{Hol}^{s+1 / 2}\left(\Omega, V_{b}\right)$ that agree on the boundary agree everywhere. The derivative of the restriction map is also a restriction map; it is injective and has a left inverse, by Theorem B. 4 (ii). Hence the restriction map $\mathcal{Z}_{0} \rightarrow \mathcal{W}_{0}$ is a holomorphic immersion.

We show that the restriction map $\mathcal{Z}_{0} \rightarrow \mathcal{W}_{0}$ is proper.
Suppose that $v_{k} \in \mathcal{Z}\left(b_{k}\right)$, that $\gamma_{k}:=v_{k} \mid \Gamma$, that $\gamma_{k}$ converges to $\gamma \in \mathcal{W}(b)$, and that $\gamma=v \mid \Gamma$ where $v \in \mathcal{Z}(b)$. We prove in four steps that $v_{k}$ converges to $v$ in $H^{s+1 / 2}(\Omega, Q)$.
Step 1. We may assume without loss of generality that each $v_{k}$ is an embedding for every $k$.
After shrinking $\mathcal{V}_{0}$ we find that $\gamma: \Gamma \rightarrow Q_{b}$ is an embedding for every $(\gamma, b) \in \mathcal{V}_{0}$. (This makes sense because $s>3 / 2$, so $\gamma$ is continuously differentiable.) If $\gamma=v \mid \Gamma$ is an embedding and $v \in \operatorname{Hol}^{s+1 / 2}\left(\Omega, V_{b}\right)$ then $v$ is an embedding. This is because $\# v^{-1}(q)$ (the number of preimages counted with multiplicity) for $q \in Q_{b} \backslash v(\Gamma)$ can only change as $q$ passes through the image of $\gamma$. As $\gamma$ is an embedding $\# v^{-1}(q)$ is either zero or one. Hence $v$ is an embedding.

Step 2. A subsequence of $v_{k}$ converges in the $C^{\infty}$ topology on every compact subset of $\operatorname{int}(\Omega)$.

If the first derivatives of $v_{k}$ are uniformly bounded then $v_{k} \mid \operatorname{int}(\Omega)$ has a $C^{\infty}$ convergent subsequence (see [16, Appendix B]). Moreover, a nonconstant holomorphic sphere in $Q$
bubbles off whenever the first derivatives of $v_{k}$ are not bounded. But bubbling cannot occur in $V$. To see this argue as follows. Suppose $z_{k}$ converges to $z_{0} \in \operatorname{int}(\Omega)$ and the derivatives of $v_{k}$ at $z_{k}$ blow up. Then the standard bubbling argument (see [16, Chapter 4]) applies. It shows that, after passing to a subsequence and modifying $z_{k}$ (without changing the limit), there are $\left(i, j_{k}\right)$-holomorphic embeddings $\varepsilon_{k}$ from the disk $\mathbb{D}_{k} \subset \mathbb{C}$, centered at zero with radius $k$, to $Q$ such that $\varepsilon_{k}(0)=z_{k}$, the family of disks $\varepsilon_{k}\left(\mathbb{D}_{k}\right)$ converges to $z_{0}$, and $v_{k} \circ \varepsilon_{k}$ converges to a nonconstant $J$-holomorphic sphere $v_{0}: S^{2}=\mathbb{C} \cup \infty \rightarrow Q_{b}$. (The convergence is uniform with all derivatives on every compact subset of $\mathbb{C}$.) The image of $v_{0}$ must intersect the nodal set $Q_{b} \cap C_{B}$. Hence there is a point $a \in \mathbb{C}=S^{2} \backslash\{\infty\}$ such that $v_{0}(a) \in Q \backslash \bar{V}$. This implies $v_{k}\left(\varepsilon_{k}(a)\right) \notin V$ for $k$ sufficiently large, contradicting the fact that $v_{k}(\Omega) \subset V$.

Step 3. A subsequence of $v_{k}$ converges to $v$ in the $C^{0}$ topology.
By Arzelà-Ascoli it suffices to show that the sequence $v_{k}$ is bounded in $C^{1}$. We treat this as a Lagrangian boundary value problem. Choose $M \subset Q_{b}$ to be a submanifold with boundary that contains the image of $v$ in its interior. Choose a smooth family of embeddings

$$
\iota_{a}: M \rightarrow Q_{a} \backslash C_{B}, \quad a \in B,
$$

such that $\iota_{b}: M \rightarrow Q_{b} \backslash C_{B}$ is the inclusion. Then the image of $\iota_{b_{k}}$ contains the image of $v_{k}$ for $k$ sufficiently large. Think of $M$ as a symplectic manifold and define the Lagrangian submanifolds $L \subset M$ and $L_{k} \subset M$ by

$$
L:=\gamma(\Gamma), \quad L_{k}:=\iota_{b_{k}}^{-1} \circ \gamma_{k}(\Gamma) .
$$

Since $s>7 / 2$ the sequence $\iota_{b_{k}}^{-1} \circ \gamma_{k}: \Gamma \rightarrow M$ converges to $\gamma$ in the $C^{3}$ topology. Hence there is a sequence of diffeomorphisms $\phi_{k}: M \rightarrow M$ such that $\phi_{k}$ converges to the identity in the $C^{3}$ topology and

$$
\phi_{k} \circ \iota_{b_{k}}^{-1} \circ \gamma_{k}=\gamma, \quad \phi_{k}\left(L_{k}\right)=L .
$$

Define

$$
\tilde{v}_{k}:=\phi_{k} \circ \iota_{b_{k}}^{-1} \circ v_{k}, \quad \tilde{J}_{k}:=\left(\phi_{k} \circ \iota_{b_{k}}^{-1}\right)_{*} J_{b_{k}},
$$

where $J_{a}$ denotes the complex structure on $Q_{a}$. Then $\tilde{J}_{k}$ converges to $\tilde{J}:=J_{b}$ in the $C^{2}$ topology, $\tilde{v}_{k}: \Omega \rightarrow M$ is a $\tilde{J}_{k}$-holomorphic curve such that $\tilde{v}_{k}(\Gamma) \subset L$ and, moreover,

$$
\begin{equation*}
\tilde{v}_{k} \mid \Gamma=\gamma: \Gamma \rightarrow L \tag{18}
\end{equation*}
$$

for all $k$. We must prove that the first derivatives of $\tilde{v}_{k}$ are uniformly bounded. Suppose by contradiction that there is a sequence $z_{k} \in \Omega$ such that

$$
c_{k}:=\left|d \tilde{v}_{k}\left(z_{k}\right)\right|=\left\|d \tilde{v}_{k}\right\|_{L^{\infty}} \rightarrow \infty .
$$

Now apply the standard rescaling argument: Assume without loss of generality that $z_{k}$ converges to $z_{0} \in \Omega$, choose a coordinate chart from a neighborhood of $z_{0}$ to the upper half plane (sending $z_{k}$ to $\zeta_{k}$ ), and compose the resulting $\tilde{J}_{k}$-holomorphic curve with
the rescaling map $\varepsilon_{k}(\zeta):=\zeta_{k}+\zeta / c_{k}$. Let $d_{k}$ be the Euclidean distance of $\zeta_{k}$ from the boundary of the upper half plane. There are two cases. If $c_{k} \cdot d_{k} \rightarrow \infty$ then a nonconstant holomorphic sphere bubbles off and the same argument as in Step 2 leads to a contradiction. If the sequence $c_{k} \cdot d_{k}$ is bounded then, by [16, Theorem B.4.2], the rescaled sequence has a subsequence that converges in the $C^{1}$ topology to a holomorphic curve $\tilde{w}:\{\zeta \in \mathbb{C}: \operatorname{im} \zeta \geq 0\} \rightarrow M$ with $\tilde{w}(\mathbb{R}) \subset L$. The choice of the rescaling factor shows that the derivative of $\tilde{w}$ has norm one at some point and so $\tilde{w}$ is nonconstant. On the other hand, since $\varepsilon_{k}$ converges to a constant, condition $\sqrt{18}$ implies that the restriction of this holomorphic curve to the boundary is constant; contradiction.
Step 4. A subsequence of $v_{k}$ converges to $v$ in the $H^{s+1 / 2}$ topology.
Let $v$ be the limit in Step 3. Then $v \mid \Gamma=\gamma$ takes values in $W_{b}$. By Step 2 it is enough to show that $v_{k}$ converges to $v$ in some neighborhood of each boundary component in the $H^{s+1 / 2}$ topology. We can identify such a neighborhood holomorphically with $\mathbb{A}(r, 1)$. Shrinking the neighborhood if necessary we may assume that $v_{k}$ maps $\mathbb{A}(r, 1)$ to $W_{b}$ for $k$ sufficiently large. By assumption and Step 2 the restriction of $v_{k}$ to $\partial \mathbb{A}(r, 1)$ converges in $H^{s}$. Hence Step 4 follows from the fact that the restriction map $H^{s+1 / 2}(\mathbb{A}(r, 1)) \rightarrow$ $H^{s}(\partial \mathbb{A}(r, 1))$ is a linear embedding onto a closed subspace (see Theorem B.4(ii)). In the notation of 10.5 below this subspace is the diagonal in $H_{r}^{s} \times H^{s}$.

Thus we have proved that every subsequence of $v_{k}$ has a further subsequence converging to $v$ in $H^{s+1 / 2}$. Hence the sequence $v_{k}$ itself converges to $v$ in the $H^{s+1 / 2}$ topology. This completes the proof of (i).

We prove (ii). It follows directly from the definitions that there is a map

$$
\operatorname{ker} D_{w_{0}, b_{0}} \rightarrow T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0} \cap T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}:(\xi, \hat{b}) \mapsto(\xi \mid \Gamma, \hat{b})
$$

This map is surjective by elliptic regularity: if $\xi: \Sigma \rightarrow w_{0}^{*} T Q$ is a continuous section with $d \pi_{B}\left(w_{0}\right) \xi=\hat{b}$ whose restriction to both $\Delta$ and $\Omega$ is of class $H^{s+1 / 2}$ and belongs to the kernel of the differential operator $D_{w_{0}}$, then $\xi$ is smooth. The map is injective by unique continuation: an element $(\xi, \hat{b}) \in \operatorname{ker} D_{w_{0}, b_{0}}$ vanishes identically if and only if the restriction of $\xi$ to the disjoint union $\Gamma$ of circles vanishes. (The fibers are connected and so $\Gamma$ intersects each component of $\Sigma$ in at least one circle.) This proves (ii).

To prove (iii), we define a map

$$
\begin{equation*}
\operatorname{coker} D_{w_{0}, b_{0}} \rightarrow \frac{T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0}}{T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0}+T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}}:[\eta] \mapsto[\hat{\gamma}, \hat{b}] \tag{19}
\end{equation*}
$$

as follows. Given $\eta \in \mathcal{Y}_{w_{0}}$ (i.e. $\eta \in \Omega^{0,1}\left(\Sigma, w_{0}^{*} T Q\right.$ ) with $d \pi\left(w_{0}\right) \eta \equiv 0$ ) choose two vector fields $\xi_{u}$ along $u_{0}:=w_{0} \mid \Delta$ and $\xi_{v}$ along $v_{0}:=w_{0} \mid \Omega$ that project each to a constant vector $\hat{b}_{u}:=d \pi_{B}\left(u_{0}\right) \xi_{u}$ and $\hat{b}_{v}:=d \pi_{B}\left(v_{0}\right) \xi_{v}$ in $T_{b_{0}} B$ and satisfy

$$
\begin{equation*}
D_{u_{0}, b_{0}}\left(\xi_{u}, \hat{b}_{u}\right)=\eta\left|\Delta, \quad D_{v_{0}, b_{0}}\left(\xi_{v}, \hat{b}_{v}\right)=\eta\right| \Omega \tag{20}
\end{equation*}
$$

The existence of $\xi_{u}$ and $\xi_{v}$ (with $\hat{b}_{u}=\hat{b}_{v}=0$ ) can be proved by imposing a Lagrangian boundary condition with high Maslov index. Define

$$
\begin{equation*}
\hat{\gamma}:=\xi_{u}\left|\Gamma-\xi_{v}\right| \Gamma: \Gamma \rightarrow \gamma_{0}^{*} T Q, \quad \hat{b}:=\hat{b}_{u}-\hat{b}_{v} . \tag{21}
\end{equation*}
$$

Given $\eta$, the pair $\left(\xi_{u} \mid \Gamma, \hat{b}_{u}\right)$ is well defined up to an additive vector in $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0}$ and ( $\xi_{v} \mid \Gamma, \hat{b}_{v}$ ) up to an additive vector in $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}$. Moreover, if $\eta \in \operatorname{im} D_{w_{0}, b_{0}}$ then there is a pair $(\xi, \hat{b}) \in \mathcal{X}_{w_{0}, b_{0}}$ such that $D_{w_{0}, b_{0}}(\xi, \hat{b})=\eta$ (see Definition 5.2) and we may choose $\xi_{u}:=\xi \mid \Delta$ and $\xi_{v}:=\xi \mid \Omega$ in 20, so that $\hat{b}_{u}=\hat{b}_{v}=\hat{b}$ and $(\hat{\gamma}, \hat{b})=(0,0)$ in 21. This shows that the equivalence class of $(\hat{\gamma}, \hat{b})$ is independent of the choice of $\xi_{u}$ and $\xi_{v}$ and depends only on the equivalence class of $\eta$ in $\mathcal{Y}_{w_{0}} / \operatorname{im} D_{w_{0}, b_{0}}$. Hence the map 19 is well defined.

We prove that 19 is injective. Let $\eta \in \mathcal{Y}_{w_{0}}$ be given, choose $\left(\xi_{u}, \hat{b}_{u}\right)$ and $\left(\xi_{v}, \hat{b}_{v}\right)$ so as to satisfy 20 , and define $(\hat{\gamma}, \hat{b}) \in T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0}$ by 21). Assume $(\hat{\gamma}, \hat{b}) \in T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0}+$ $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}$. Then there are vector fields $\xi_{u}^{\prime}$ along $u_{0}$ and $\xi_{v}^{\prime}$ along $v_{0}$, as well as tangent vectors $\hat{b}_{u}^{\prime}, \hat{b}_{v}^{\prime} \in T_{b_{0}} B$ such that $d \pi\left(u_{0}\right) \xi_{u}^{\prime} \equiv \hat{b}_{u}^{\prime}, d \pi\left(u_{0}\right) \xi_{v}^{\prime} \equiv \hat{b}_{v}^{\prime}$, and

$$
\begin{gathered}
D_{u_{0}, b_{0}}\left(\xi_{u}^{\prime}, \hat{b}_{u}^{\prime}\right)=0, \quad D_{v_{0}, b_{u}}\left(\xi_{v}^{\prime}, \hat{b}_{v}^{\prime}\right)=0, \\
\hat{\gamma}=\xi_{u}^{\prime}\left|\Gamma-\xi_{v}^{\prime}\right| \Gamma, \quad \hat{b}:=\hat{b}_{u}^{\prime}-\hat{b}_{v}^{\prime} .
\end{gathered}
$$

Hence, replacing $\left(\xi_{u}, \hat{b}_{u}\right)$ by $\left(\xi_{u}-\xi_{u}^{\prime}, \hat{b}_{u}-\hat{b}_{u}^{\prime}\right)$ and $\left(\xi_{v}, \hat{b}_{v}\right)$ by $\left(\xi_{v}-\xi_{v}^{\prime}, \hat{b}_{v}-\hat{b}_{v}^{\prime}\right)$, we may assume without loss of generality that $\hat{\gamma}=0$ and $\hat{b}=0$ in 21. Thus $\xi_{u}\left|\Gamma=\xi_{v}\right| \Gamma$. In other words, there is a continuous vector field $\xi$ along $w_{0}$ such that $\xi \mid \Delta=\xi_{u}$ and $\xi \mid \Omega=\xi_{v}$. Since $D_{w_{0}} \xi=\eta$ is smooth it follows from elliptic regularity that $\xi$ is smooth and hence $\eta \in \operatorname{im} D_{w_{0}, b_{0}}$. This shows that the map 19 is injective as claimed.

That (19) is surjective follows from the next two assertions.
(a) Each element of the quotient space $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0} /\left(T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0}+T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}\right)$ can be represented by a smooth vertical vector field along $\gamma_{0}$.
(b) For every smooth vertical vector field $\hat{\gamma}$ along $\gamma_{0}$ there exist smooth vertical vector fields $\xi_{u}$ along $u_{0}$ and $\xi_{v}$ along $v_{0}$ such that $\hat{\gamma}=\xi_{u}\left|\Gamma-\xi_{v}\right| \Gamma$ and the $(0,1)$-form $\eta$ along $w_{0}$ defined by $\eta \mid \Delta:=D_{u_{0}, b_{0}}\left(\xi_{u}, \hat{b}_{u}\right)$ and $\eta \mid \Omega:=D_{u_{0}, b_{0}}\left(\xi_{v}, \hat{b}_{v}\right)$ is smooth.
To prove (b) choose holomorphic coordinates $\tau+i \theta \in[-\delta, \delta]+i \mathbb{R} / 2 \pi \mathbb{Z}$ near each component of $\Gamma$ so that the component is $\{\tau=0\}$ and $\Omega$ is $\{\tau \geq 0\}$. Choose a complex trivialization of the vertical tangent bundle over this annulus. In this trivialization a $(0,1)$ form over the annulus has the form $\frac{1}{2}(\eta d s-i \eta d t)$ with $\eta:[-\delta, \delta] \times S^{1} \rightarrow \mathbb{C}$ and the operator $D=D_{w_{0}, b_{0}}$ has the form

$$
D \xi=\partial_{\tau} \xi+i \partial_{\theta} \xi+S \xi
$$

where $S:[-\delta, \delta] \times S^{1} \rightarrow \operatorname{End}_{\mathbb{R}}(\mathbb{C})$ is a smooth map. We seek three smooth sections $\xi_{u}$ over $\{\tau \leq 0\}, \xi_{v}$ over $\{\tau \geq 0\}$, and $\eta$ over the whole annulus (of the vertical tangent bundle) such that

$$
\eta\left|\{\tau \leq 0\}=D \xi_{u}, \quad \eta\right|\{\tau \geq 0\}=D \xi_{v},
$$

and

$$
\begin{equation*}
\xi_{v}(0, \theta)-\xi_{u}(0, \theta)=\xi_{0}(\theta):=-\hat{\gamma}(\theta) . \tag{22}
\end{equation*}
$$

We take $\xi_{u}:=0$ and $\xi_{v}$ in the form

$$
\xi_{v}(\tau, \theta)=\sum_{k=0}^{\infty} \frac{c_{k}(\tau, \theta)}{k!} \tau^{k}, \quad c_{k}(\tau, \theta)= \begin{cases}c_{k}(0, \theta) & \text { for } 0 \leq \tau \leq \delta_{k} \\ 0 & \text { for } \tau \geq 2 \delta_{k}\end{cases}
$$

where $2 \delta_{k}<\delta$ and each $c_{k}$ is smooth on $[0, \delta] \times S^{2}$. To satisfy condition 22 we must choose $c_{0}(0, \theta)=\xi_{0}(\theta)$. To make $\eta$ continuous we must choose $\xi_{v}$ such that

$$
\partial_{\tau} \xi_{v}(0, \theta)+i \partial_{\theta} \xi_{v}(0, \theta)+S(0, \theta) \xi_{v}(0, \theta)=0
$$

and hence

$$
c_{1}(0, \theta)=\partial_{\tau} \xi_{v}(0, \theta)=-i \partial_{\theta} \xi_{0}(\theta)-S(0, \theta) \xi_{0}(\theta)
$$

More generally, once $c_{0}, \ldots, c_{k}$ have been chosen to make $\eta$ of class $C^{k-1}$ the function $\theta \mapsto c_{k+1}(0, \theta)$ is uniquely determined by $\xi_{0}$ and the condition that $\eta$ be of class $C^{k}$. Finally, choose $\delta_{k}$ converging sufficiently rapidly to zero and define $c_{k}(\tau, \theta):=$ $\beta\left(\tau / \delta_{k}\right) c_{k}(0, \theta)$ for a suitable cutoff function $\beta$ so that the series for $\xi_{v}$ converges in the $C^{\ell}$ norm for every $\ell$. Note that our argument follows the construction, due to Émile Borel, of a smooth function with a prescribed Taylor series at a point.

To prove (a) we first observe that every smooth pair $(\hat{\gamma}, \hat{b}) \in T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0}$ is equivalent in the quotient $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0} /\left(T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0}+T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}\right)$ to a smooth vertical vector field. Namely, choose any vector field $\xi^{\prime}$ along $v_{0}$ that projects to $\hat{b}$, and choose a vertical vector field $\xi^{\prime \prime}$ along $v_{0}$ such that $\xi:=\xi^{\prime}+\xi^{\prime \prime}$ satisfies $D_{v_{0}} \xi=0$ (as we did in the proof of $(\mathrm{b}))$. Then $(\xi \mid \Gamma, \hat{b}) \in T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}$ and hence $(\hat{\gamma}-\xi \mid \Gamma, 0)$ is a vertical vector field equivalent to $(\hat{\gamma}, \hat{b})$. Now consider the subspace of all elements of the quotient $T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{W}_{0} /\left(T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{U}_{0}+T_{\left(\gamma_{0}, b_{0}\right)} \mathcal{V}_{0}\right)$ that can be represented by smooth vertical vector fields. By what we have just proved, this subspace is dense and, by (b), it is finitedimensional. Hence this subspace must be equal to the entire quotient and this proves (a). Thus we have proved (a) and (b) and hence the operator $\sqrt{19}$ ) is surjective. This proves (iii). Part (iv) is an immediate consequence of (ii) and (iii). This completes the proof of Theorem 9.5
Remark 9.6. The strategy for the proof of the universal unfolding theorem is to assign to each unfolding ( $\pi_{A}: P \rightarrow A, R_{*}, a_{0}$ ) of the marked nodal Riemann surface ( $\Sigma, s_{*}, v, j$ ) a family of Hilbert submanifolds $\mathcal{U}_{a}, \mathcal{V}_{a} \subset \mathcal{W}_{a}$ as in 9.3 parametrized by $a \in A$. Transversality will then imply that for each $a$ near $a_{0}$ there is a unique intersection point $\left(\gamma_{a}, b_{a}\right) \in \mathcal{U}_{a} \cap \mathcal{V}_{a}$ near $\left(\gamma_{0}, b_{0}\right)$. Then the fiber isomorphisms $f_{a}: P_{a} \rightarrow Q_{b_{a}}$ determined by the $\gamma_{a}$ as in Lemma 9.4 will fit together to determine the required morphisms $P \rightarrow Q$ of nodal families. The key point is to show that the submanifolds $\mathcal{U}_{a}$ fit together to form a complex submanifold

$$
\mathcal{U}:=\bigsqcup_{a \in A} \mathcal{U}_{a} \subset \mathcal{W}:=\bigsqcup_{a \in A} \mathcal{W}_{a}
$$

(see Theorem 11.9 below). We begin by studying a local model near a given nodal point in the next section.

## 10. The local model

10.1. Consider the standard node defined as the map

$$
N \rightarrow \operatorname{int}(\mathbb{D}):(x, y) \mapsto x y, \quad N:=\left\{(x, y) \in \mathbb{D}^{2}:|x y|<1\right\} .
$$

For $a \in \operatorname{int}(\mathbb{D})$ and $b \in \mathbb{C}$ define

$$
N_{a}:=\left\{(x, y) \in \mathbb{D}^{2}: x y=a\right\}, \quad Q_{b}:=\left\{(x, y) \in \mathbb{C}^{2}: x y=b\right\}
$$

We study the set of all quadruples $(a, \xi, \eta, b)$ where $a, b \in \mathbb{C}$ are close to 0 and

$$
(\xi, \eta): N_{a} \rightarrow Q_{b}
$$

is a holomorphic map. If $a \neq 0$ this means $\xi(z), \eta(z)$ are holomorphic functions on the annulus $|a| \leq|z| \leq 1$ that are close to the identity, and satisfy the condition

$$
\begin{equation*}
x y=a \Rightarrow \xi(x) \eta(y)=b \tag{23}
\end{equation*}
$$

for $|a| \leq|x| \leq 1$ and $|a| \leq|y| \leq 1$. If $a \neq 0$, this condition implies that $b \neq 0$. When $a=0$, the functions $\xi$ and $\eta$ are defined on the closed unit disk and vanish at the origin; hence $b=0$.
10.2. Fix $s>1 / 2$ and let $H^{s}=H^{s}\left(S^{1}, \mathbb{C}^{n}\right)$ be the Sobolev space as in B.1. We think of an element of $H^{s}$ as a power series

$$
\begin{equation*}
\zeta(z)=\sum_{n \in \mathbb{Z}} \zeta_{n} z^{n} \tag{24}
\end{equation*}
$$

For $r>0$ the rescaling map $z \mapsto r z$ maps the unit circle to the circle of radius $r$. Denote by $\zeta_{r}$ the result of conjugating $\zeta$ by this map, i.e.

$$
\zeta_{r}(z):=r^{-1} \zeta(r z) .
$$

The norm $\left\|\zeta_{r}\right\|_{s}$ is finite if and only if the series $\zeta$ converges to an $H^{s}$ function on the circle of radius $r$.
10.3. For $\delta>0$ define the open set $\mathcal{W}_{\delta} \subset \mathbb{C} \times H^{s} \times H^{s} \times \mathbb{C}$ by

$$
\mathcal{W}_{\delta}:=\left\{(a, \xi, \eta, b):\|\xi-\mathrm{id}\|_{s}<\delta,\|\eta-\mathrm{id}\|_{s}<\delta,|a|<\delta\right\} .
$$

Define $\mathcal{U}_{\delta} \subset \mathcal{W}_{\delta}$ to be the set of those quadruples $(a, \xi, \eta, b) \in \mathcal{W}_{\delta}$ which satisfy (23). More precisely if $(a, \xi, \eta, b) \in \mathcal{W}_{\delta}$, then for $a \neq 0$ we have

$$
(a, \xi, \eta, b) \in \mathcal{U}_{\delta} \Leftrightarrow\left\{\begin{array}{l}
\left\|\xi_{|a|}\right\|_{s}<\infty,\left\|\eta_{|a|}\right\|_{s}<\infty, \text { and } \\
\xi(x) \eta\left(a x^{-1}\right)=b \text { for }|a| \leq|x| \leq 1,
\end{array}\right.
$$

while for $a=0$ we have

$$
(0, \xi, \eta, b) \in \mathcal{U}_{\delta} \Leftrightarrow b=0 \text { and } \xi(0)=\eta(0)=0
$$

Thus $\mathcal{U}_{\delta}$ is the space of (boundary values of) local holomorphic fiber isomorphisms in the standard model. The main result of this section is that $\mathcal{U}_{\delta}$ is a manifold:

Theorem 10.4. Let $s>1 / 2$. Then, for $\delta>0$ sufficiently small, the set $\mathcal{U}_{\delta}$ is a complex submanifold of the open set $\mathcal{W}_{\delta} \subset \mathbb{C} \times H^{s} \times H^{s} \times \mathbb{C}$.

The proof occupies the rest of this section. Using the Hardy space decomposition defined in 10.5 we formulate three propositions which define a map $\mathcal{T}$ whose graph lies in $\mathcal{U}_{\delta}$. We then prove six lemmas, then we prove the three propositions, and finally we prove that the graph of $\mathcal{T}$ is exactly equal to $\mathcal{U}_{\delta}$.
10.5. A holomorphic function $\zeta(z)$ defined on an annulus centered at the origin has a Laurent expansion of the form (24). We write $\zeta=\zeta_{+}+\zeta_{-}$where

$$
\zeta_{+}(z):=\sum_{n>0} \zeta_{n} z^{n}, \quad \zeta_{-}(z):=\sum_{n \leq 0} \zeta_{n} z^{n}
$$

For $r>0$ and $s>1 / 2$ introduce the norm

$$
\|\zeta\|_{r, s}:=\sqrt{\sum_{n \in \mathbb{Z}}(1+|n|)^{2 s} r^{2 n-2}\left|\zeta_{n}\right|^{2}}
$$

so that $\zeta_{+}$converges inside the circle of radius $r$ if $\left\|\zeta_{+}\right\|_{r, s}<\infty$ and $\zeta_{-}$converges outside the circle of radius $r$ if $\left\|\zeta_{-}\right\|_{r, s}<\infty$. Let

$$
H_{r}^{s}:=\left\{\zeta:\|\zeta\|_{r, s}<\infty\right\}
$$

and $H_{r, \pm}^{s}$ be the subspace of those $\zeta$ for which $\zeta=\zeta_{ \pm}$so we have the Hardy space decomposition

$$
H_{r}^{s}=H_{r,+}^{s} \oplus H_{r,-}^{s} .
$$

Then $H^{s}=H_{1}^{s}$ and $\|\cdot\|_{s}=\|\cdot\|_{1, s}$. We abbreviate

$$
H_{ \pm}^{s}:=H_{1, \pm}^{s} .
$$

We view the ball of radius $\delta$ about id in the Hilbert space $H_{r}^{s}$ as a space of $H^{s}$-maps from the circle of radius $r$ to a neighborhood of this circle; the norm on $H_{r}^{s}$ is defined so that conjugation by the rescaling map $z \mapsto r z$ induces an isometry $H_{r}^{s} \rightarrow H^{s}: \zeta \rightarrow \zeta_{r}$, i.e.

$$
\begin{equation*}
\|\zeta\|_{r, s}=\left\|\zeta_{r}\right\|_{s}, \quad \zeta_{r}(z):=r^{-1} \zeta(r z) . \tag{25}
\end{equation*}
$$

Proposition 10.6 (Existence). For every $s>1 / 2$ there are positive constants $\delta$ and $c$ such that the following holds. If $a \in \mathbb{C}$ with $0<r:=\sqrt{|a|} \leq 1$ and $\xi_{+}, \eta_{+} \in H_{+}^{s}$ satisfy

$$
\begin{equation*}
\left\|\xi_{+}-\mathrm{id}\right\|_{s}<\delta, \quad\left\|\eta_{+}-\mathrm{id}\right\|_{s}<\delta \tag{26}
\end{equation*}
$$

then there exists a triple $\left(b, \xi_{-}, \eta_{-}\right) \in \mathbb{C} \times H_{r^{2},-}^{s} \times H_{r^{2},-}^{s}$ such that $\xi:=\xi_{+}+\xi_{-}$and $\eta:=\eta_{+}+\eta_{-}$satisfy the equation

$$
\begin{equation*}
\xi(x) \eta\left(a x^{-1}\right)=b \tag{27}
\end{equation*}
$$

for $r^{2} \leq|x| \leq 1$ and

$$
\begin{equation*}
\left|b a^{-1}-\xi_{1} \eta_{1}\right|+\left\|\xi_{-}\right\|_{r, s}+\left\|\eta_{-}\right\|_{r, s} \leq 2 c r\left(\left\|\xi_{+}-\mathrm{id}\right\|_{s}+\left\|\eta_{+}-\mathrm{id}\right\|_{s}\right) \tag{28}
\end{equation*}
$$

Proposition 10.7 (Uniqueness). For every $s>1 / 2$ there exist positive constants $\delta$ and $\varepsilon$ such that the following holds. If $a, b, b^{\prime} \in \mathbb{C}, \xi_{+}, \eta_{+} \in H_{+}^{s}$ and $\xi_{-}, \eta_{-}, \xi_{-}^{\prime}, \eta_{-}^{\prime} \in H_{r,-}^{s}$ with $0<r:=\sqrt{|a|}<1$ satisfy 26) and

$$
\left\|\xi_{-}\right\|_{r, s}<\varepsilon, \quad\left\|\eta_{-}\right\|_{r, s}<\varepsilon, \quad \sup _{|x|=r}\left|\xi_{-}^{\prime}(x)\right|<r \varepsilon, \quad \sup _{|y|=r}\left|\eta_{-}^{\prime}(y)\right|<r \varepsilon
$$

and if $\left(a, \xi:=\xi_{+}+\xi_{-}, \eta:=\eta_{+}+\eta_{-}, b\right)$ and $\left(a, \xi^{\prime}:=\xi_{+}+\xi_{-}^{\prime}, \eta^{\prime}:=\eta_{+}+\eta_{-}^{\prime}, b^{\prime}\right)$ satisfy 27] for $|x|=r$ then $\left(\xi_{-}, \eta_{-}, b\right)=\left(\xi_{-}^{\prime}, \eta_{-}^{\prime}, b^{\prime}\right)$.
10.8. Fix a constant $s>1 / 2$. Choose positive constants $\delta$ and $\varepsilon$ such that Proposition 10.7 holds. Shrinking $\delta$ if necessary we may assume that Proposition 10.6 holds with the same constant $\delta$ and a suitable constant $c>0$. Let

$$
H_{+}^{s}(\mathrm{id}, \delta):=\left\{\zeta \in H_{+}^{s}:\|\zeta-\mathrm{id}\|_{s}<\delta\right\}
$$

and define

$$
\mathcal{T}: \mathbb{D} \times H_{+}^{s}(\mathrm{id}, \delta) \times H_{+}^{s}(\mathrm{id}, \delta) \rightarrow \mathbb{C} \times H_{-}^{s} \times H_{-}^{s}
$$

by the conditions that $\mathcal{T}\left(a, \xi_{+}, \eta_{+}\right)=\left(b, \xi_{-}, \eta_{-}\right)$is the triple constructed in Proposition 10.6 for $a \neq 0$ and

$$
\mathcal{T}\left(0, \xi_{+}, \eta_{+}\right):=(0,0,0)
$$

(In defining $\mathcal{T}$ we used the fact that $H_{r,-}^{s} \subset H_{-}^{s}$ for $r \leq 1$.)
Proposition 10.9. The map $\mathcal{T}$ is continuous. It is holomorphic for $|a|<1$.
Lemma 10.10 (A priori estimates). There is a constant $c>0$ such that, for $\delta>0$ sufficiently small, the following holds. If $(a, \xi, \eta, b) \in \mathcal{U}_{\delta}$ and $a \neq 0$ then

$$
\left|b a^{-1}-1\right|<c \delta, \quad \sup _{|a| \leq|x| \leq 1}\left|\xi(x) x^{-1}-1\right| \leq c \delta, \quad \sup _{|a| \leq|y| \leq 1}\left|\eta(y) y^{-1}-1\right| \leq c \delta
$$

Proof. Rewrite $\xi(x) \eta\left(a x^{-1}\right)=b$ as

$$
a \frac{\xi(x)}{x^{2}}=a b \frac{x^{-2}}{\eta\left(a x^{-1}\right)}
$$

Using the substitution $y=a x^{-1}, d y=-a x^{-2} d x$ we get

$$
a \oint_{|x|=1} \frac{\xi(x) d x}{x^{2}}=b \oint_{|x|=1} \frac{a x^{-2} d x}{\eta\left(a x^{-1}\right)}=b \oint_{|y|=|a|} \frac{d y}{\eta(y)}=b \oint_{|y|=1} \frac{d y}{\eta(y)}
$$

where all the contour integrals are counterclockwise. By the Sobolev embedding theorem, there is a constant $c$ such that $|\zeta(z)| \leq c\|\zeta\|_{s}$ for $\zeta \in H^{s}$ and $|z|=1$. This gives the estimate

$$
\left|\frac{\xi(x)}{x^{2}}-\frac{1}{x}\right|=|\xi(x)-x| \leq c\|\xi-\mathrm{id}\|_{s} \leq c \delta
$$

for $|x|=1$. If $\|\eta-\mathrm{id}\|_{s}<\delta \leq 1 / 2 c$ then, by the Sobolev embedding theorem again, $|\eta(y)-y|<1 / 2$ and so $|\eta(y)|>1 / 2$ for $|y|=1$. Hence

$$
\left|\frac{1}{\eta(y)}-\frac{1}{y}\right|=\frac{|\eta(y)-y|}{|\eta(y)|} \leq 2 c\|\eta-\mathrm{id}\|_{s} \leq 2 c \delta
$$

for $|y|=1$. Hence the contour integrals are within $4 \pi c \delta$ of $2 \pi i$ and so, if we enlarge $c$, then $b / a$ is within $c \delta$ of 1 as required.

By symmetry the third inequality follows from the second; we prove the second. Using the Sobolev inequality we have

$$
\sup _{|x|=1}\left|\frac{\xi(x)}{x}-1\right| \leq c \delta, \quad \sup _{|y|=1}\left|\frac{\eta(y)}{y}-1\right| \leq c \delta
$$

Now let $y:=a x^{-1}$ and $|x|=|a|$. Then $|y|=1$ and

$$
\frac{\xi(x)}{x}-1=\frac{b}{a} \frac{y-\eta(y)}{\eta(y)}+\frac{b}{a}-1
$$

Hence

$$
\sup _{|x|=|a|}\left|\frac{\xi(x)}{x}-1\right| \leq\left|\frac{b}{a}\right| \sup _{|y|=1}\left|\frac{y-\eta(y)}{\eta(y)}\right|+\left|\frac{b}{a}-1\right| \leq c \delta
$$

By the maximum principle this implies

$$
\sup _{|a| \leq|x| \leq 1}\left|\frac{\xi(x)}{x}-1\right| \leq c \delta
$$

This proves the lemma.
10.11. The proofs of Propositions $10.6,10.7$, and 10.9 are based on a version of the implicit function theorem for the map

$$
\mathcal{F}_{r}: \mathbb{C} \times H_{r}^{s} \times H_{r}^{s} \rightarrow H^{s}
$$

defined by

$$
\begin{equation*}
\mathcal{F}_{r}(\lambda, \xi, \eta)(z):=r^{-2} \xi(r z) \eta\left(r z^{-1}\right)-\lambda \tag{29}
\end{equation*}
$$

for $|z|=1$ and $r>0$. The zeros of $\mathcal{F}_{r}$ are solutions of 27) with $a=r^{2}$ and $b=\lambda a$. Note that $\mathcal{F}_{r}(1, \mathrm{id}, \mathrm{id})=0$ for every $r>0$. The differential of $\mathcal{F}_{r}$ at the point $(1, \mathrm{id}, \mathrm{id})$ will be denoted by

$$
\mathcal{D}_{r}:=d \mathcal{F}_{r}(1, \mathrm{id}, \mathrm{id}): \mathbb{C} \times H_{r}^{s} \times H_{r}^{s} \rightarrow H^{s}
$$

Thus

$$
\mathcal{D}_{r}(\hat{\lambda}, \hat{\xi}, \hat{\eta})(z)=r^{-1} z^{-1} \hat{\xi}(r z)+r^{-1} z \hat{\eta}\left(r z^{-1}\right)-\hat{\lambda}
$$

We shall need six lemmata. They are routine consequences of well known facts and rescaling. To ease the exposition we relegate the proofs of the first five to the end of the section and omit the proof of the sixth entirely. (The last proof is just the proof of the implicit function theorem keeping track of the estimates.)

Lemma 10.12 (Sobolev estimate). Denote by $\mathbb{A}(r, R) \subset \mathbb{C}$ the closed annulus $r \leq|z|$ $\leq R$. For every $s>1 / 2$ there is a constant $c>0$ such that

$$
\|\zeta\|_{L^{\infty}(\mathbb{A}(r, R))} \leq c\left(r\left\|\zeta_{-}\right\|_{r, s}+R\left\|\zeta_{+}\right\|_{R, s}\right)
$$

for all $r$ and $R$ and every holomorphic function $\zeta(z)$ on the annulus $r \leq|z| \leq R$.
Proof. This follows from Lemma A. 2 and the maximum principle.
Lemma 10.13 (Product estimate). For every $s>1 / 2$ there is a positive constant $C$ such that, for any two functions $\xi, \eta \in H^{s}$, we have

$$
\|\xi \eta\|_{s} \leq C\|\xi\|_{s}\|\eta\|_{s}, \quad\|\xi \eta\|_{s} \leq C\left(\|\xi\|_{s}\|\eta\|_{L^{\infty}\left(S^{1}\right)}+\|\xi\|_{L^{\infty}\left(S^{1}\right)}\|\eta\|_{s}\right) .
$$

Proof. Lemma A. 3 and Corollary A. 11
Lemma 10.14 (Linear estimate). For $\hat{\xi}_{-}, \hat{\eta}_{-} \in H_{r,-}^{s}$ and $\hat{\lambda} \in \mathbb{C}$ we have

$$
\left\|\hat{\xi}_{-}\right\|_{r, s}^{2}+\left\|\hat{\eta}_{-}\right\|_{r, s}^{2}+|\hat{\lambda}|^{2} \leq\left\|\mathcal{D}_{r}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)\right\|_{s}^{2} .
$$

Proof. The formula

$$
\mathcal{D}_{r}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)(z)=r^{-1} z^{-1} \hat{\xi}_{-}(r z)+r^{-1} z \hat{\eta}_{-}\left(r z^{-1}\right)-\hat{\lambda}
$$

shows that

$$
\mathcal{D}_{r}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)=\mathcal{D}_{1}\left(\hat{\lambda},\left(\hat{\xi}_{-}\right)_{r},\left(\hat{\eta}_{-}\right)_{r}\right) .
$$

Hence, by 25 it suffices to prove the lemma for $r=1$. Then

$$
\mathcal{D}_{1}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)(z)=\sum_{n<0} \hat{\xi}_{n+1} z^{n}-\hat{\lambda}+\sum_{n>0} \hat{\eta}_{1-n} z^{n}
$$

so

$$
\begin{aligned}
\left\|\mathcal{D}_{1}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)\right\|_{s}^{2} & =\sum_{n<0}(1+|n|)^{2 s}\left|\hat{\xi}_{n+1}\right|^{2}+|\hat{\lambda}|^{2}+\sum_{n>0}(1+|n|)^{2 s}\left|\hat{\eta}_{1-n}\right|^{2} \\
& =\sum_{n \leq 0}(2+|n|)^{2 s}\left|\hat{\xi}_{n}\right|^{2}+|\hat{\lambda}|^{2}+\sum_{n \leq 0}(2+|n|)^{2 s}\left|\hat{\eta}_{n}\right|^{2} \\
& \geq\left\|\hat{\xi}_{-}\right\|_{s}^{2}+|\hat{\lambda}|^{2}+\left\|\hat{\eta}_{-}\right\|_{s}^{2} .
\end{aligned}
$$

This proves the lemma.
Lemma 10.15 (Approximate solution). For every $s>1 / 2$ there is a constant $c>0$ such that

$$
\left\|\mathcal{F}_{r}\left(\xi_{1} \eta_{1}, \xi_{+}, \eta_{+}\right)\right\|_{s} \leq c r\left(\left\|\xi_{+}-\mathrm{id}\right\|_{s}+\left\|\eta_{+}-\mathrm{id}\right\|_{s}\right)
$$

for every pair $\xi_{+}, \eta_{+} \in H_{+}^{s}$ with $\left\|\xi_{+}\right\|_{s} \leq 1,\left\|\eta_{+}\right\|_{s} \leq 1$, and every $r \in(0,1]$.

Proof. The constant is $c=4 \sqrt{3} C$ where $C$ is the constant of Lemma 10.13 . We first prove the inequality

$$
\begin{equation*}
\left\|\mathcal{F}_{1}\left(\xi_{1} \eta_{1}, \xi_{+}, \eta_{+}\right)\right\|_{s} \leq 2 \sqrt{3} C\left(\left\|\xi_{+}-\xi_{1} \mathrm{id}\right\|_{s}+\left\|\eta_{+}-\eta_{1} \mathrm{id}\right\|_{s}\right) \tag{30}
\end{equation*}
$$

Since

$$
\mathcal{F}_{1}\left(\xi_{1} \eta_{1}, \xi_{+}, \eta_{+}\right)(z)=\xi_{+}(z) \eta_{+}\left(z^{-1}\right)-\xi_{1} \eta_{1}=\sum_{k \neq 0}\left(\sum_{n>0} \xi_{n+k} \eta_{n}\right) z^{k}+\sum_{n>1} \xi_{n} \eta_{n}
$$

we have

$$
\begin{aligned}
\left\|\mathcal{F}_{1}\left(\xi_{1} \eta_{1}, \xi_{+}, \eta_{+}\right)\right\|_{s}^{2}= & \sum_{k \neq 0}(1+|k|)^{2 s}\left|\sum_{n>0} \xi_{n+k} \eta_{n}\right|^{2}+\left|\sum_{n>1} \xi_{n} \eta_{n}\right|^{2} \\
\leq & \sum_{k>0}(1+k)^{2 s}\left(\sum_{n>0}\left|\xi_{n+k} \eta_{n}\right|\right)^{2}+\left(\sum_{n>1}\left|\xi_{n} \eta_{n}\right|\right)^{2} \\
& +\sum_{k>0}(1+k)^{2 s}\left(\sum_{n>k}\left|\xi_{n-k} \eta_{n}\right|\right)^{2} \\
\leq & 3 C^{2}\left(\left\|\xi_{+}-\xi_{1} \mathrm{id}\right\|_{s}^{2}\left\|\eta_{+}\right\|_{s}^{2}+\left\|\xi_{+}\right\|_{s}^{2}\left\|\eta_{+}-\eta_{1} \mathrm{id}\right\|_{s}^{2}\right)
\end{aligned}
$$

The last inequality follows from Lemma 10.13 , note that each sum omits either $\xi_{1}$ or $\eta_{1}$ or both. The inequality (30) follows by taking the square root of the last estimate and using the fact that $\left\|\xi_{+}\right\|_{s} \leq 2$ and $\left\|\eta_{+}\right\|_{s} \leq 2$.

The formula

$$
\mathcal{F}_{r}\left(\xi_{1} \eta_{1}, \xi_{+}, \eta_{+}\right)(z)=r^{-2} \xi_{+}(r z) \eta_{+}\left(r z^{-1}\right)-\xi_{1} \eta_{1}
$$

shows that

$$
\mathcal{F}_{r}\left(\xi_{1} \eta_{1}, \xi_{+}, \eta_{+}\right)=\mathcal{F}_{1}\left(\xi_{1} \eta_{1},\left(\xi_{+}\right)_{r},\left(\eta_{+}\right)_{r}\right)
$$

Note that the operation $\xi \mapsto \xi_{r}$ leaves the coefficient $\xi_{1}$ unchanged. Hence, by 30), we have

$$
\begin{aligned}
\left\|\mathcal{F}_{r}\left(\xi_{1} \eta_{1}, \xi_{+}, \eta_{+}\right)\right\|_{s} & =\left\|\mathcal{F}_{1}\left(\xi_{1} \eta_{1},\left(\xi_{+}\right)_{r},\left(\eta_{+}\right)_{r}\right)\right\|_{s} \\
& \leq 2 \sqrt{3} C\left(\left\|\left(\xi_{+}\right)_{r}-\xi_{1} \mathrm{id}\right\|_{s}+\left\|\left(\eta_{+}\right)_{r}-\eta_{1} \mathrm{id}\right\|_{s}\right) \\
& =2 \sqrt{3} C\left(\left\|\xi_{+}-\xi_{1} \mathrm{id}\right\|_{r, s}+\left\|\eta_{+}-\eta_{1} \mathrm{id}\right\|_{r, s}\right) \\
& \leq 2 \sqrt{3} C r\left(\left\|\xi_{+}-\xi_{1} \mathrm{id}\right\|_{s}+\left\|\eta_{+}-\eta_{1} \mathrm{id}\right\|_{s}\right) \\
& \leq 4 \sqrt{3} C r\left(\left\|\xi_{+}-\mathrm{id}\right\|_{s}+\left\|\eta_{+}-\mathrm{id}\right\|_{s}\right)
\end{aligned}
$$

This proves the lemma.
Lemma 10.16 (Quadratic estimate). For every $s>1 / 2$ there is a constant $c>0$ such that

$$
\left\|\left(d \mathcal{F}_{r}(\lambda, \xi, \eta)-\mathcal{D}_{r}\right)(\hat{\lambda}, \hat{\xi}, \hat{\eta})\right\|_{s} \leq c\left(\|\eta-\mathrm{id}\|_{r, s}\|\hat{\xi}\|_{r, s}+\|\xi-\mathrm{id}\|_{r, s}\|\hat{\eta}\|_{r, s}\right)
$$

for all $\xi, \eta, \hat{\xi}, \hat{\eta} \in H_{r}^{s}$ and $\lambda, \hat{\lambda} \in \mathbb{C}$.

Proof. We have

$$
d \mathcal{F}_{r}(\lambda, \xi, \eta)(\hat{\lambda}, \hat{\xi}, \hat{\eta})(z)=r^{-2} \hat{\xi}(r z) \eta\left(r z^{-1}\right)+r^{-2} \xi(r z) \hat{\eta}\left(r z^{-1}\right)-\hat{\lambda}
$$

and hence

$$
\left(d \mathcal{F}_{r}(\lambda, \xi, \eta)-\mathcal{D}_{r}\right)(\hat{\lambda}, \hat{\xi}, \hat{\eta})(z)=r^{-2} \hat{\xi}(r z)(\eta-\mathrm{id})\left(r z^{-1}\right)+r^{-2}(\xi-\mathrm{id})(r z) \hat{\eta}\left(r z^{-1}\right)
$$

So the result follows from Lemma 10.13 with $c=C$.
Lemma 10.17 (Inverse function theorem). Let $f: U \rightarrow V$ be a smooth map between Banach spaces and $D: U \rightarrow V$ be a Banach space isomorphism. Let $u_{0} \in U$ and suppose that there is a constant $\rho>0$ such that

$$
\begin{equation*}
\left\|D^{-1}\right\| \leq 1, \quad\left\|f\left(u_{0}\right)\right\|_{V} \leq \rho / 2 \tag{31}
\end{equation*}
$$

and, for every $u \in U$,

$$
\begin{equation*}
\left\|u-u_{0}\right\|_{U} \leq \rho \Rightarrow\|d f(u)-D\| \leq 1 / 2 \tag{32}
\end{equation*}
$$

Then there is a unique element $u \in U$ such that

$$
\left\|u-u_{0}\right\|_{U} \leq \rho, \quad f(u)=0 .
$$

Moreover, $\left\|u-u_{0}\right\|_{U} \leq 2\left\|f\left(u_{0}\right)\right\|_{V}$.
Proof. Standard.
Proof of Proposition 10.6 Throughout we fix a constant $s>1 / 2$ and a constant $c \geq 1$ such that the assertions of Lemmata 10.12, 10.15 and 10.16 hold with these constants $s$ and $c$. Choose positive constants $\varepsilon, \rho$, and $\delta$ such that

$$
\begin{equation*}
3 c \varepsilon<1 / 2, \quad c \sqrt{2 \delta^{2}+\rho^{2}} \leq 1 / 2, \quad 2 c \delta \leq \varepsilon / 2, \quad \rho:=\sqrt{3} \varepsilon . \tag{33}
\end{equation*}
$$

We prove the assertion with these constants $c$ and $\delta$.
Assume first that $a$ is a positive real number and set $r:=\sqrt{a}$. Fix a pair $\left(\xi_{+}, \eta_{+}\right) \in$ $H_{+}^{s} \times H_{+}^{s}$ satisfying 26. Let

$$
U:=\mathbb{C} \times H_{r,-}^{s} \times H_{r,-}^{s}, \quad V:=H^{s},
$$

and consider the map $f: U \rightarrow V$ defined by

$$
\begin{equation*}
f(u):=\mathcal{F}_{r}\left(\lambda, \xi_{+}+\xi_{-}, \eta_{+}+\eta_{-}\right), \quad u:=\left(\lambda, \xi_{-}, \eta_{-}\right) . \tag{34}
\end{equation*}
$$

Let $D:=\mathcal{D}_{r}: U \rightarrow V$ and $u_{0}:=\left(\xi_{1} \eta_{1}, 0,0\right)$. Then, by Lemma 10.14

$$
\begin{equation*}
\left\|D^{-1}\right\|_{\mathcal{L}(V, U)} \leq 1 \tag{35}
\end{equation*}
$$

and, by Lemma 10.15 and 33),

$$
\begin{equation*}
\left\|f\left(u_{0}\right)\right\|_{V} \leq c r\left(\left\|\xi_{+}-\mathrm{id}\right\|_{s}+\left\|\eta_{+}-\mathrm{id}\right\|_{s}\right) \leq 2 c \delta \leq \varepsilon / 2 \leq \rho / 2 \tag{36}
\end{equation*}
$$

In this notation the operator $d f(u)-D: U \rightarrow V$ is the restriction of the operator $d \mathcal{F}_{r}(\lambda, \xi, \eta)-\mathcal{D}_{r}: \mathbb{C} \times H_{r}^{s} \times H_{r}^{s} \rightarrow H^{s}$ to the subspace $U$, so by Lemma 10.16 we have

$$
\|d f(u)-D\|_{\mathcal{L}(U, V)} \leq c \sqrt{\|\eta-\mathrm{id}\|_{r, s}^{2}+\|\xi-\mathrm{id}\|_{r, s}^{2}}
$$

for $u=\left(\lambda, \xi_{-}, \eta_{-}\right) \in U$ and $\xi:=\xi_{+}+\xi_{-}$and $\eta:=\eta_{+}+\eta_{-}$. Note that $\|\zeta\|_{r, s} \leq\|\zeta\|_{s}$ for $\zeta \in H_{+}^{s}$ and $0<r \leq 1$. Hence

$$
\|d f(u)-D\|_{\mathcal{L}(U, V)} \leq c \sqrt{\left\|\xi_{+}-\mathrm{id}\right\|_{s}^{2}+\left\|\eta_{+}-\mathrm{id}\right\|_{s}^{2}+\left\|\xi_{-}\right\|_{r, s}^{2}+\left\|\eta_{-}\right\|_{r, s}^{2}}
$$

for $u=\left(\lambda, \xi_{-}, \eta_{-}\right) \in U$. Since $\left\|\xi_{+}-\mathrm{id}\right\|_{s} \leq \delta$ and $\left\|\eta_{+}-\mathrm{id}\right\|_{s} \leq \delta$ we have

$$
\begin{equation*}
\left\|u-u_{0}\right\|_{U} \leq \rho \Rightarrow\|d f(u)-D\|_{\mathcal{L}(U, V)} \leq c \sqrt{2 \delta^{2}+\rho^{2}} \leq 1 / 2 \tag{37}
\end{equation*}
$$

for every $u=\left(\lambda, \xi_{-}, \eta_{-}\right) \in U$. Here we have used (33).
It follows from (35), (36), and (37) that the assumptions of Lemma 10.17 are satisfied. Hence there is a unique point $u \in U$ such that

$$
\left\|u-u_{0}\right\|_{U} \leq \rho, \quad f(u)=0
$$

and this unique point satisfies

$$
\begin{equation*}
\left\|u-u_{0}\right\|_{U} \leq 2\left\|f\left(u_{0}\right)\right\|_{V} \leq \varepsilon \tag{38}
\end{equation*}
$$

Thus, for every $\left(\xi_{+}, \eta_{+}\right) \in H_{+}^{s} \times H_{+}^{s}$ satisfying 26, we have found a unique triple $\left(\lambda, \xi_{-}, \eta_{-}\right) \in U$ such that $\xi:=\xi_{+}+\xi_{-}$and $\eta:=\eta_{+}+\eta_{-}$satisfy

$$
\mathcal{F}_{r}(\lambda, \xi, \eta)=0, \quad\left\|\xi_{-}\right\|_{r, s} \leq \varepsilon, \quad\left\|\eta_{-}\right\|_{r, s} \leq \varepsilon, \quad\left|\lambda-\xi_{1} \eta_{1}\right| \leq \varepsilon
$$

That the quadruple ( $a, \xi, \eta, b$ ) also satisfies the estimate (28) follows from (36) and (38).
Next we prove that this quadruple $(a, \xi, \eta, b)$ satisfies $\xi(z) \neq 0$ and $\eta(z) \neq 0$ for $r \leq|z| \leq 1$. To see this note that

$$
\left\|(\zeta / \mathrm{id})_{+}\right\|_{s}=\sqrt{\sum_{n \geq 2} n^{2 s}\left|\zeta_{n}\right|^{2}} \leq\left\|\zeta_{+}\right\|_{s}
$$

and

$$
r\left\|(\zeta / \mathrm{id})_{-}\right\|_{r, s}=\sqrt{\left|\zeta_{1}\right|^{2}+\sum_{n \leq 0}(2-n)^{2 s} r^{2 n-2}\left|\zeta_{n}\right|^{2}} \leq\left\|\zeta_{+}\right\|_{s}+2\left\|\zeta_{-}\right\|_{r, s}
$$

Hence

$$
\begin{aligned}
\sup _{r \leq|x| \leq 1}\left|\xi(x) x^{-1}-1\right| & \leq c\left(\left\|(\xi / \mathrm{id}-1)_{+}\right\|_{s}+r\left\|(\xi / \mathrm{id}-1)_{-}\right\|_{r, s}\right) \\
& \leq 2 c\left(\left\|\xi_{+}-\mathrm{id}\right\|_{s}+\|\xi-\|_{r, s}\right) \leq 2 c(\delta+\varepsilon) \leq 1 / 2
\end{aligned}
$$

Here the first inequality follows from Lemma 10.12 and the last uses the fact that $2 c \varepsilon \leq$ $1 / 3$ and $2 c \delta \leq \varepsilon / 2 \leq 1 / 6$. Thus we have proved that $\xi$ and $\eta$ do not vanish on the closed annulus $r \leq|z| \leq 1$. Now extend $\xi$ and $\eta$ to the annulus $r^{2} \leq|z| \leq 1$ by the formulas

$$
\xi(x):=\frac{b}{\eta\left(a x^{-1}\right)}, \quad \eta(y):=\frac{b}{\xi\left(a y^{-1}\right)}, \quad r^{2} \leq|x|,|y| \leq r .
$$

The resulting functions $\xi$ and $\eta$ are continuous across the circle of radius $r$ by 27). Hence they are holomorphic on the large annulus $r^{2}<|z|<1$. Since 27, holds on the middle circle $|x|=r$ it holds on the annulus $r^{2} \leq|x| \leq 1$. This proves the proposition for positive real numbers $a$.

To prove the proposition for general $a$ we use the following "rotation trick". Fix a constant $\theta \in \mathbb{R}$. Given $\xi, \eta \in H_{+}^{s} \oplus H_{r,-}^{s}$ and $a, b \in \mathbb{C}$ define $\tilde{\xi}, \tilde{\eta} \in H_{+}^{s} \oplus H_{r,-}^{s}$ and $\tilde{a}, \tilde{b} \in \mathbb{C}$ by

$$
\tilde{\xi}(z):=e^{-i \theta} \xi\left(e^{i \theta} z\right), \quad \tilde{\eta}(z):=e^{-i \theta} \eta\left(e^{i \theta} z\right), \quad \tilde{a}:=e^{-2 i \theta} a, \quad \tilde{b}:=e^{-2 i \theta} b .
$$

Then $a, b, \xi, \eta$ satisfy 27, if and only if $\tilde{a}, \tilde{b}, \tilde{\xi}, \tilde{\eta}$ satisfy 27. Hence the result for general $a$ can be reduced to the special case by choosing $\theta$ such that $\tilde{a}:=e^{-2 i \theta} a$ is a positive real number. This proves the proposition.

Proof of Proposition 10.7 The general case can be reduced to the case $a>0$ by the rotation trick in the proof of Proposition 10.6. Hence we assume $a=r^{2}$ and $r>0$. Choose positive constants $c$ and $C$ such that the assertions of Lemmata 10.12, 10.13 and 10.16 hold with these constants. Choose $\delta$ and $\varepsilon$ such that

$$
2 c \delta \leq 1, \quad 8 C(1+c) \varepsilon<1
$$

Let $(a, \xi, \eta, b)$ and $\left(a^{\prime}, \xi^{\prime}, \eta^{\prime}, b^{\prime}\right)$ satisfy the assumptions of Proposition 10.7 with these constants $\delta$ and $\varepsilon$ and define

$$
\lambda:=b / a=b / r^{2}, \quad \lambda^{\prime}:=b^{\prime} / a^{\prime}=b^{\prime} / r^{2} .
$$

Then

$$
\begin{equation*}
r^{-2} \xi(r z) \eta\left(r z^{-1}\right)=\lambda, \quad r^{-2} \xi^{\prime}(r z) \eta^{\prime}\left(r z^{-1}\right)=\lambda^{\prime}, \quad|z|=1 . \tag{39}
\end{equation*}
$$

Denote by $L_{r}: \mathbb{C} \times H_{r,-}^{s} \times H_{r,-}^{s} \rightarrow H^{s}$ the linear operator given by

$$
L_{r}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)(z):=r^{-2} \hat{\xi}_{-}(r z) \eta_{+}\left(r z^{-1}\right)+r^{-2} \xi_{+}(r z) \hat{\eta}_{-}\left(r z^{-1}\right)-\hat{\lambda}
$$

In the notation of 10.11 the operator $L_{r}$ is the restriction of the differential of $\mathcal{F}_{r}$ at $\left(\lambda, \xi_{+}, \eta_{+}\right)$(for any $\lambda$ ) to the subspace $\mathbb{C} \times H_{r,-}^{s} \times H_{r,-}^{s}$. Since $c \delta \leq 1 / 2$ it follows from Lemmata 10.14 and 10.16 that the operator $L_{r}$ is invertible and the norm of the inverse is bounded by 2 :

$$
\begin{equation*}
|\hat{\lambda}|^{2}+\left\|\hat{\xi}_{-}\right\|_{r, s}^{2}+\left\|\hat{\eta}_{-}\right\|_{r, s}^{2} \leq 4\left\|L_{r}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)\right\|_{s}^{2} \tag{40}
\end{equation*}
$$

Let us denote by $Q_{r}: H_{r,-}^{s} \times H_{r,-}^{s} \rightarrow H^{s}$ the quadratic form

$$
Q_{r}\left(\xi_{-}, \eta_{-}\right)(z):=r^{-2} \xi_{-}(r z) \eta_{-}\left(r z^{-1}\right)
$$

Then, by Lemma 10.13, we have

$$
\begin{equation*}
\left\|Q_{r}\left(\xi_{-}, \eta_{-}\right)\right\|_{s} \leq C r^{-1}\left(\left\|\xi_{-}\right\|_{r, s} \sup _{|y|=r}\left|\eta_{-}(y)\right|+\left\|\eta_{-}\right\|_{r, s} \sup _{|x|=r}\left|\xi_{-}(x)\right|\right) \tag{41}
\end{equation*}
$$

Now let

$$
\hat{\lambda}:=\lambda^{\prime}-\lambda, \quad \hat{\xi}_{-}:=\xi^{\prime}-\xi, \quad \hat{\eta}_{-}:=\eta^{\prime}-\eta
$$

Then the difference of the two equations in 39) can be expressed in the form
$L_{r}\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)=Q_{r}\left(\xi_{-}, \eta_{-}\right)-Q_{r}\left(\xi_{-}^{\prime}, \eta_{-}^{\prime}\right)=-Q_{r}\left(\hat{\xi}_{-}, \eta_{-}\right)-Q_{r}\left(\xi_{-}, \hat{\eta}_{-}\right)-Q_{r}\left(\hat{\xi}_{-}, \hat{\eta}_{-}\right)$.
Abbreviate

$$
\hat{\zeta}:=\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right), \quad\|\hat{\zeta}\|_{r, s}:=\sqrt{|\hat{\lambda}|^{2}+\left\|\hat{\xi}_{-}\right\|_{r, s}^{2}+\left\|\hat{\eta}_{-}\right\|_{r, s}^{2}}
$$

Then

$$
\begin{aligned}
\|\hat{\zeta}\|_{r, s} \leq & 2\left\|L_{r} \hat{\zeta}\right\|_{s} \leq 2\left(\left\|Q_{r}\left(\hat{\xi}_{-}, \eta_{-}\right)\right\|_{s}+\left\|Q_{r}\left(\xi_{-}, \hat{\eta}_{-}\right)\right\|_{s}+\left\|Q_{r}\left(\hat{\xi}_{-}, \hat{\eta}_{-}\right)\right\|_{s}\right) \\
\leq & 2 C\left(\|\xi-\|_{r, s}+\left\|\eta_{-}\right\|_{r, s}\right)\|\hat{\zeta}\|_{r, s}+2 C r^{-1}\left(\sup _{|x|=r}\left|\hat{\xi}_{-}(x)\right|+\sup _{|y|=r}\left|\hat{\eta}_{-}(y)\right|\right)\|\hat{\zeta}\|_{r, s} \\
\leq & 2 C(1+c)\left(\left\|\xi_{-}\right\|_{r, s}+\left\|\eta_{-}\right\|_{r, s}\right)\|\hat{\zeta}\|_{r, s} \\
& +2 C r^{-1}\left(\sup _{|x|=r}\left|\xi_{-}^{\prime}(x)\right|+\sup _{|y|=r}\left|\eta_{-}^{\prime}(y)\right|\right)\|\hat{\zeta}\|_{r, s} \\
\leq & 8 C(1+c) \varepsilon\|\hat{\zeta}\|_{r, s} .
\end{aligned}
$$

Here the first inequality follows from (40), the second from the triangle inequality, the third from Lemma 10.13 and 41, the fourth from Lemma 10.12, and the last from the assumptions of the proposition. Since $8 C(1+c) \varepsilon<1$ it follows that $\hat{\zeta}=0$. This proves the proposition.

## Proof of Proposition 10.9

Step 1. The map $\mathcal{T}$ is continuous.
Continuity for $a>0$ is an easy consequence of the proof of Proposition 10.6. The map $f$ defined in $\sqrt[34]{ }$ depends continuously on the parameters $\xi_{+}, \eta_{+}, r$, and $r=\sqrt{a}$ depends continuously on $a$. For complex nonzero $a$ we can choose $\theta$ in the rotation trick to depend continuously on $a$. To prove continuity for $a=0$ we deduce from (28) that there is a constant $c>0$ such that

$$
\left\|\mathcal{T}\left(a, \xi_{+}, \eta_{+}\right)\right\|:=\sqrt{|b|^{2}+\left\|\xi_{-}\right\|_{s}^{2}+\left\|\eta_{-}\right\|_{s}^{2}} \leq c|a| .
$$

Here we used the fact that $\|\zeta\|_{s} \leq r\|\zeta\|_{r, s}$ for $\zeta \in H_{r,-}^{s}$.
Step 2. Let $\xi_{+}, \eta_{+} \in H_{+}^{s}(\mathrm{id}, \delta)$ and $a \in \mathbb{D} \backslash 0$ and define $\xi:=\xi_{+}+\xi_{-}$and $\eta:=\eta_{+}+\eta_{-}$, where $\left(b, \xi_{-}, \eta_{-}\right):=\mathcal{T}\left(a, \xi_{+}, \eta_{+}\right)$. Then the linear operator

$$
L: \mathbb{C} \times H_{r,-}^{s} \times H_{r,-}^{s} \rightarrow H_{r}^{s}
$$

defined by

$$
L\left(\hat{b}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)(x):=\hat{\xi}_{-}(x) \eta\left(a x^{-1}\right)+\xi(x) \hat{\eta}\left(a x^{-1}\right)-\hat{b}
$$

is invertible.
In the notation of the proof of Proposition 10.6 the operator $L$ is conjugate to $d f(u)$. Specifically,

$$
L\left(\hat{\lambda} r^{2}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)_{r}=r d f(u)\left(\hat{\lambda}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)
$$

when $a=r^{2}$. The operator $d f(u)$ is invertible by 35) and 37). For general $a$ use the rotation trick from the end of the proof of Proposition 10.6

Step 3. The map $\mathcal{T}$ is continuously differentiable for $0<|a|<1$.
We formulate a related problem. Define a partial rescaling operator

$$
R_{r}: H^{s} \rightarrow H_{+}^{s} \oplus H_{r,-}^{s}, \quad\left(R_{r} \xi\right)(z):=\xi_{+}(z)+r \xi_{-}\left(r^{-1} z\right)
$$

The operator $R_{r}$ is a Hilbert space isometry for every $r \in(0,1]$. Let

$$
\mathcal{X}:=\mathbb{C} \times \mathbb{C} \times H^{s} \times H^{s}, \quad \mathcal{Y}:=H^{s} .
$$

There is a splitting $\mathcal{X}=\mathcal{X}_{+} \oplus \mathcal{X}_{-}$where

$$
\mathcal{X}_{+}:=\mathbb{C} \times H_{+}^{s} \times H_{+}^{s}, \quad \mathcal{X}_{-}:=\mathbb{C} \times H_{-}^{s} \times H_{-}^{s}
$$

Let $\mathcal{U} \subset \mathcal{X}$ denote the open set $\{0<|a|<1\}$ and define $\tilde{\mathcal{F}}: \mathcal{U} \rightarrow \mathcal{Y}$ by

$$
\tilde{\mathcal{F}}(a, b, \xi, \eta)(z):=\left(R_{r} \xi\right)(r z) \cdot\left(R_{r} \eta\right)\left(a r^{-1} z^{-1}\right)-b, \quad r:=\sqrt{|a|} .
$$

Define $\tilde{\mathcal{T}}: \mathcal{U} \cap \mathcal{X}_{+} \rightarrow \mathcal{X}_{-}$by

$$
\tilde{\mathcal{T}}\left(a, \xi_{+}, \eta_{+}\right):=\left(b,\left(\xi_{-}\right)_{r},\left(\eta_{-}\right)_{r}\right), \quad\left(b, \xi_{-}, \eta_{-}\right):=\mathcal{T}\left(a, \xi_{+} \cdot \eta_{+}\right)
$$

(Recall that $\zeta_{r}(z):=r^{-1} \zeta(r z)$ for $\zeta \in H_{r}^{s}$ and $|z|=1$.) By construction the graph of $\tilde{\mathcal{T}}$ is contained in the zero set of $\tilde{\mathcal{F}}$. By Step 2 the derivative of $\tilde{\mathcal{F}}$ in the direction $\tilde{\mathcal{X}}_{-}$is an invertible operator at every point in the graph of $\tilde{\mathcal{T}}$. Hence, by the implicit function theorem, $\tilde{\mathcal{T}}$ is continuously differentiable. Define the map $\mathcal{R}: \mathcal{U} \rightarrow \mathcal{U}$ by

$$
\mathcal{R}(a, b, \xi, \eta):=\left(a, b, R_{r} \xi, R_{r} \eta\right), \quad r:=\sqrt{|a|} .
$$

This map is continuously differentiable and

$$
\operatorname{graph}(\mathcal{T})=\mathcal{R} \circ \operatorname{graph}(\tilde{\mathcal{T}})
$$

Here $\operatorname{graph}(\mathcal{T})$ denotes the map $\left(a, \xi_{+}, \eta_{+}\right) \mapsto(a, b, \xi, \eta)$ given by $\left(b, \xi_{-}, \eta_{-}\right):=$ $\mathcal{T}\left(a, \xi_{+}, \eta_{+}\right)$. Similarly for $\operatorname{graph}(\tilde{\mathcal{T}})$. Hence $\operatorname{graph}(\mathcal{T})$ is continuously differentiable for $0<|a|<1$ and so is $\mathcal{T}$.

Step 4. The map $\mathcal{T}$ is holomorphic for $0<|a|<1$.

As $\mathcal{T}$ is differentiable we have

$$
d \mathcal{T}\left(a, \xi_{+}, \eta_{+}\right)\left(\hat{a}, \hat{\xi}_{+}, \hat{\eta}_{+}\right)=\left(\hat{b}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)
$$

for $\hat{a} \in \mathbb{C}$ and $\hat{\xi}_{+}, \hat{\eta}_{+} \in H_{+}^{s}$ where $\hat{\xi}_{-}, \hat{\eta}_{-} \in H_{r,-}^{s}$ and $\hat{b} \in \mathbb{C}$ are determined by the equation

$$
\begin{equation*}
L\left(\hat{b}, \hat{\xi}_{-}, \hat{\eta}_{-}\right)(x)=-\hat{\xi}_{+}(x) \eta\left(a x^{-1}\right)-\xi(x) \hat{\eta}_{+}\left(a x^{-1}\right)-\xi(x) \eta^{\prime}\left(a x^{-1}\right) \hat{a} x^{-1} \tag{42}
\end{equation*}
$$

for $|x|=r:=\sqrt{|a|}$. Here $L: \mathbb{C} \times H_{r,-}^{s} \times H_{r,-}^{s} \rightarrow H^{s}$ is the operator of Step 2. Since $L$ is complex linear so is $d \mathcal{T}\left(a, \xi_{+}, \eta_{+}\right)$.

Step 5. The map $\mathcal{T}$ is holomorphic for $|a|<1$.
That $\mathcal{T}$ is holomorphic near $a=0$ follows from Step 4, continuity, and the Cauchy integral formula. More precisely, suppose $X$ and $Y$ are complex Hilbert spaces and $\mathcal{T}$ : $\mathbb{C} \times X \rightarrow Y$ is a continuous map which is holomorphic on $(\mathbb{C} \backslash 0) \times X$. Then

$$
\mathcal{T}(a, x)=\frac{1}{2 \pi} \int_{0}^{2 \pi} \mathcal{T}\left(a+e^{i \theta} \hat{a}, x+e^{i \theta} \hat{x}\right) d \theta
$$

and

$$
d \mathcal{T}(a, x)(\hat{a}, \hat{x})=\frac{1}{2 \pi} \int_{0}^{2 \pi} e^{-i \theta} \mathcal{T}\left(a+e^{i \theta} \hat{a}, x+e^{i \theta} \hat{x}\right) d \theta
$$

for $a, \hat{a} \in \mathbb{C}$ and $x, \hat{x} \in X$ with $a \neq 0$. In the case at hand $\mathcal{T}(a, x)$ converges uniformly to zero as $|a|$ tends to zero (see the proof of Step 1). By the Cauchy integral formula, this implies that $d \mathcal{T}(a, x)$ converges uniformly to zero in the operator norm as $|a|$ tends to zero. This proves the proposition.

Proof of Theorem 10.4 Fix a constant $s>1 / 2$ and choose $\delta, c$, and $\varepsilon$ such that Propositions 10.6 and 10.7 hold. Shrinking $\delta$ we may assume $4 c \delta<\varepsilon$. We prove that the graph of $\mathcal{T}$ intersects $\mathcal{W}_{\delta}$ in $\mathcal{U}_{\delta}$. By definition

$$
\operatorname{graph}(\mathcal{T}) \cap \mathcal{W}_{\delta} \subset \mathcal{U}_{\delta}
$$

To prove the converse choose $(a, \xi, \eta, b) \in \mathcal{U}_{\delta}$. If $a=0$ then $\xi_{-}=\eta_{-}=0$ and $b=0$ so $(a, \xi, \eta, b)$ belongs to the graph of $\mathcal{T}$. Hence assume $a \neq 0$ and let $r:=\sqrt{|a|}$. Then $\left\|\xi_{+}-\mathrm{id}\right\|_{s}<\delta$ and $\left\|\eta_{+}-\mathrm{id}\right\|_{s}<\delta$. So, by Proposition 10.6, there is an element $\left(a, \xi^{\prime}, \eta^{\prime}, b^{\prime}\right) \in \mathcal{W}_{\delta} \cap \operatorname{graph}(\mathcal{T})$ satisfying $\xi_{+}^{\prime}=\xi_{+}, \eta_{+}^{\prime}=\eta_{+}$, and

$$
\left\|\xi_{-}^{\prime}\right\|_{r, s} \leq 4 c r \delta<\varepsilon, \quad\left\|\eta_{-}^{\prime}\right\|_{r, s} \leq 4 c r \delta<\varepsilon
$$

We claim that $\xi=\xi^{\prime}, \eta=\eta^{\prime}$, and $b=b^{\prime}$. By Proposition 10.7 it suffices to show that

$$
\sup _{|x|=r}\left|\xi_{-}(x)\right|<r \varepsilon, \quad \sup _{|y|=r}\left|\eta_{-}(y)\right|<r \varepsilon .
$$

By symmetry we need only prove the first inequality. By the triangle inequality

$$
\begin{equation*}
\sup _{|x|=r}\left|\xi_{-}(x)\right| \leq \sup _{|x|=r}|\xi(x)-x|+\sup _{|x|=r}\left|\xi_{+}(x)-x\right| \tag{43}
\end{equation*}
$$

By Lemma 10.10 we estimate the first term on the right by

$$
\begin{equation*}
\sup _{|x|=r}|\xi(x)-x| \leq c r \delta . \tag{44}
\end{equation*}
$$

For the second term we have, by Lemma 10.12,

$$
\sup _{|x|=r}\left|\xi_{+}(x)-x\right|=r \sup _{|z|=1}\left|\left(\xi_{+}-\mathrm{id}\right)_{r}(z)\right| \leq r c\left\|\left(\xi_{+}-\mathrm{id}\right)_{r}\right\|_{s}=c r\left\|\xi_{+}-\mathrm{id}\right\|_{r, s} .
$$

But the series for $\xi_{+}-$id has only positive powers and $r \leq 1$ so

$$
\left\|\xi_{+}-\mathrm{id}\right\|_{r, s} \leq\left\|\xi_{+}-\mathrm{id}\right\|_{s} \leq\|\xi-\mathrm{id}\|_{s} \leq \delta .
$$

Combining the last two lines gives

$$
\begin{equation*}
\sup _{|x|=r}\left|\xi_{+}(x)-x\right| \leq c r \delta . \tag{45}
\end{equation*}
$$

Now use (43), (44), and (45) and shrink $\delta$ so $2 c \delta<\varepsilon$.
We close this section with two lemmas that will be useful in what follows.
Lemma 10.18. Fix $s>1 / 2$ and choose $\delta>0$ as in Theorem 10.4 Let $A \subset \operatorname{int}(\mathbb{D}) \times \mathbb{C}^{m}$ be an open set and

$$
A \rightarrow \mathcal{U}_{\delta}:(a, t) \mapsto\left(a, \xi_{a, t}, \eta_{a, t}, b_{a, t}\right)
$$

be a holomorphic map. Then the map

$$
\Phi:\left\{(x, y, t) \in \mathbb{C}^{2+m}: x, y \in \operatorname{int}(\mathbb{D}),(x y, t) \in A\right\} \rightarrow \mathbb{C} \times \mathbb{C}
$$

given by

$$
\Phi(x, y, t):=\Phi_{t}(x, y):=\left(\xi_{x y, t}(x), \eta_{x y, t}(y)\right)
$$

is holomorphic.
Proof. The evaluation map

$$
H^{s} \cap H_{r^{2}}^{s} \times\left\{z \in \mathbb{C}: r^{2}<|z|<1\right\} \rightarrow \mathbb{C}:(\zeta, z) \mapsto \zeta(z)
$$

is holomorphic. It follows that the map $(x, y, t) \mapsto \Phi_{t}(x, y)$ is holomorphic in the domain $x y \neq 0$. We prove that $\Phi$ is continuous. Suppose $x_{i} \rightarrow x \neq 0, y_{i} \rightarrow 0$, and $t_{i} \rightarrow t$. Then $\xi_{x_{i} y_{i}, t_{i}}$ converges to $\xi_{0, t}$, uniformly in a neighborhood of $x$, and hence $\xi_{x_{i} y_{i}, t_{i}}\left(x_{i}\right)$ converges to $\xi_{0, t}(x)$. Moreover, if $c$ and $\delta$ are the constants of Lemma 10.10, then

$$
\left|\eta_{x_{i} y_{i}, t_{i}}\left(y_{i}\right)\right| \leq(c \delta+1)\left|y_{i}\right|
$$

and so $\eta_{x_{i} y_{i}, t_{i}}\left(y_{i}\right)$ converges to $\eta_{0, t}(0)=0$. Hence $\Phi_{t_{i}}\left(x_{i}, y_{i}\right)$ converges to $\Phi_{t}(x, 0)=$ $\left(\xi_{0, t}(x), 0\right)$. Hence $\Phi$ is continuous at every point $(x, 0, t)$ with $x \neq 0$. By symmetry, $\Phi$ is continuous at every point $(0, y, t)$ with $y \neq 0$. That $\Phi$ is continuous at every point $(0,0, t)$ follows again from Lemma 10.10 . Since $\Phi$ is continuous and is holomorphic in $x y \neq 0$, it follows from the Cauchy integral formula that $\Phi$ is holomorphic.

Lemma 10.19. Let $\xi_{0}, \eta_{0}: \operatorname{int}(\mathbb{D}) \rightarrow \mathbb{C}$ be two holomorphic functions satisfying $\xi_{0}(0)=$ $\eta_{0}(0)=0$ and $\xi_{0}^{\prime}(0) \neq 0, \eta_{0}^{\prime}(0) \neq 0$. Then there are neighborhoods $U_{1}$ and $U_{2}$ of $(0,0)$ in $\mathbb{C}^{2}$ and $B_{1}$ and $B_{2}$ of 0 in $\mathbb{C}$ and holomorphic diffeomorphisms $\Phi:=(\xi, \eta): U_{1} \rightarrow U_{2}$ and $\zeta: B_{1} \rightarrow B_{2}$ such that

$$
\xi(x, 0)=\xi_{0}(x), \quad \eta(0, y)=\eta_{0}(y), \quad \xi(x, y) \eta(x, y)=\zeta(x y)
$$

for $x, y$ near 0 .
Proof. Replacing $\xi_{0}$ and $\eta_{0}$ by $\xi_{0}^{\prime}(0)^{-1} \xi_{0}$ and $\eta_{0}^{\prime}(0)^{-1} \eta_{0}$ we may assume that $\xi_{0}^{\prime}(0)=$ $\eta_{0}^{\prime}(0)=1$. Replacing $\xi_{0}(x)$ and $\eta_{0}(y)$ by $\varepsilon^{-1} \xi_{0}(\varepsilon x)$ and $\varepsilon^{-1} \eta_{0}(\varepsilon y)$ we may assume that the power series for $\xi_{0}$ and $\eta_{0}$ lie in $H_{+}^{s}(\mathrm{id}, \delta)$ with $\delta>0$ as in 10.8 For $z \in \mathbb{D}$ define $\alpha_{z}, \beta_{z} \in H_{-}^{s}$ by $\left(\zeta(z), \alpha_{z}, \beta_{z}\right):=\mathcal{T}\left(z, \xi_{0}, \eta_{0}\right)$ and then define $\xi(x, y):=\xi_{0}(x)+$ $\alpha_{x y}(x)$ and $\eta(x, y):=\eta_{0}(y)+\beta_{x y}(y)$. Then $\Phi$ is holomorphic by Lemma 10.18 A direct calculation shows that $d \Phi(0,0)$ is the identity so $\Phi$ is a local diffeomorphism. The desired identities follow from the definition of $\mathcal{T}$. To prove that $\zeta^{\prime}(0)=1$ differentiate the identity $\xi \eta=\zeta$ twice.

## 11. Hardy decompositions

In this section we redo Section 9 in parametrized form. We will use the implicit function theorem on a manifold of maps. The main difficulty in defining a suitable manifold of maps is that the nodal family $\pi_{A}$ is not locally trivial because the homotopy type of the fiber changes. To circumvent this difficulty we use the local model of Section 10 for a neighborhood of the nodal set and suitable trivializations for the complement (see Definitions 11.2 and 11.6 .
11.1. Throughout this section $\left(\pi_{A}: P \rightarrow A, R_{*}, a_{0}\right)$ and ( $\left.\pi_{B}: Q \rightarrow B, S_{*}, b_{0}\right)$ are nodal unfoldings,

$$
f_{0}: P_{a_{0}} \rightarrow Q_{b_{0}}
$$

is a fiber isomorphism, and $p_{1}, \ldots, p_{k}$ are the nodal points of the central fiber $P_{a_{0}}$, so $q_{i}:=f_{0}\left(p_{i}\right)($ for $i=1, \ldots, k)$ are the nodal points of the central fiber $Q_{b_{0}}$. Let $m:=$ $\operatorname{dim}_{\mathbb{C}}(A)$ and $d:=\operatorname{dim}_{\mathbb{C}}(B)$. Let $C_{A} \subset P$ and $C_{B} \subset Q$ denote the critical points of $\pi_{A}$ and $\pi_{B}$ respectively.

Definition 11.2. A Hardy decomposition for $\left(\pi_{A}, R_{*}, a_{0}\right)$ is a decomposition

$$
P=M \cup N, \quad \partial M=\partial N=M \cap N
$$

into manifolds with boundary such that

$$
N=N_{1} \cup \cdots \cup N_{k}
$$

each $N_{i}$ is a neighborhood of $p_{i}$, the closures of the $N_{i}$ are pairwise disjoint, $N$ is disjoint from the elements of $R_{*}$, and $N$ is the domain of a nodal coordinate system. This consists of three sequences of holomorphic maps

$$
\left(x_{i}, y_{i}\right): N_{i} \rightarrow \mathbb{D}^{2}, \quad z_{i}: A \rightarrow \mathbb{C}, \quad t_{i}: A \rightarrow \mathbb{C}^{m-1}
$$

such that each map

$$
A \rightarrow \mathbb{D} \times \mathbb{C}^{m-1}: a \mapsto\left(z_{i}(a), t_{i}(a)\right)
$$

is a holomorphic coordinate system, each map

$$
N_{i} \rightarrow \mathbb{D}^{2} \times \mathbb{C}^{m-1}: p \mapsto\left(x_{i}(p), y_{i}(p), t_{i}\left(\pi_{A}(p)\right)\right)
$$

is a holomorphic coordinate system and

$$
x_{i}\left(p_{i}\right)=y_{i}\left(p_{i}\right)=0, \quad z_{i} \circ \pi_{A}=x_{i} y_{i} .
$$

(Note that here $N_{i}$ has a boundary whereas its analog $U_{i}$ in 9.1 was open.) Restricting to a fiber gives a decomposition

$$
P_{a}=M_{a} \cup N_{a}, \quad M_{a}:=M \cap P_{a}, \quad N_{a}:=N \cap P_{a}
$$

where $M_{a}$ is a Riemann surface with boundary and each component of $N_{a}$ is either a closed annulus or a pair of transverse closed disks. The nodal coordinate system determines a trivialization

$$
\begin{equation*}
\iota: A \times \Gamma \rightarrow \partial N, \quad \Gamma:=\bigcup_{i=1}^{k}\{(i, 1),(i, 2)\} \times S^{1}, \tag{46}
\end{equation*}
$$

where $\iota^{-1}$ is the disjoint union of the maps

$$
\begin{array}{ll}
\pi \times x_{i}: \partial_{1} N_{i} \rightarrow A \times S^{1}, & \partial_{1} N_{i}:=\left\{\left|x_{i}\right|=1\right\}, \\
\pi \times y_{i}: \partial_{2} N_{i} \rightarrow A \times S^{1}, & \partial_{2} N_{i}:=\left\{\left|y_{i}\right|=1\right\} .
\end{array}
$$

The indexing is so that $\iota\left(A \times(i, 1) \times S^{1}\right)=\partial_{1} N_{i}$ and $\iota\left(A \times(i, 2) \times S^{1}\right)=\partial_{2} N_{i}$. For $a \in A$ define $\iota_{a}: \Gamma \rightarrow \partial N$ by $\iota_{a}(\lambda):=\iota(a, \lambda)$.

Lemma 11.3. After shrinking $A$ and $B$ if necessary, there is a Hardy decomposition $P=$ $M \cup N$ as in 11.2 and there are open subsets

$$
U=U_{1} \cup \cdots \cup U_{k}, \quad V, \quad W:=U \cap V
$$

of $Q$ and functions $\xi_{i}, \eta_{i}, \zeta_{i}, \tau_{i}$ as described in 9.1 such that

$$
f_{0}\left(M_{a_{0}}\right) \subset V_{b_{0}}, \quad f_{0}\left(N_{a_{0}}\right) \subset U_{b_{0}}
$$

and

$$
\xi_{i} \circ f_{0} \circ x_{i}^{-1}(x, 0,0)=x, \quad \eta_{i} \circ f_{0} \circ y_{i}^{-1}(0, y, 0)=y
$$

for $x, y \in \mathbb{D}$.

Proof. Choose any Hardy decomposition $P=M \cup N$ as in 11.2 as well as open subsets $U=U_{1} \cup \cdots \cup U_{k}, V, W$ of $Q$ and functions $\xi_{i}, \eta_{i}, \zeta_{i}, \tau_{i}$ as described in 9.1. Read $\xi_{i} \circ f_{0} \circ x_{i}^{-1}(x)$ for $\xi_{0}(x)$ and $\eta_{i} \circ f_{0} \circ y_{i}^{-1}(y)$ for $\eta_{0}(y)$ in Lemma 10.19 let $\Phi$ and $\zeta$ be as in the conclusion of that lemma, and replace $\left(\xi_{i}, \eta_{i}\right)$ by $\Phi^{-1} \circ\left(\xi_{i}, \eta_{i}\right)$ and $\zeta_{i}$ by $\zeta^{-1} \circ \zeta_{i}$. This requires shrinking $U_{i}($ and $B)$. Then shrink $N$ so that $f_{0}\left(N_{a_{0}}\right) \subset U_{b_{0}}$ and enlarge $V$ so that $f_{0}\left(M_{a_{0}}\right) \subset V_{b_{0}}$.
11.4. We use a Hardy decomposition to mimic the construction of 9.3 with $a \in A$ as a parameter. Choose a Hardy decomposition $P=M \cup N$ for $\left(\pi_{A}, R_{*}, a_{0}\right)$, open subsets $U=U_{1} \cup \cdots \cup U_{k}, V, W$ of $Q$, and functions $\xi_{i}, \eta_{i}, \zeta_{i}, \tau_{i}$ as described in 9.1, such that the conditions of Lemma 11.3 are satisfied. Fix an integer $s+1 / 2>1$ and define an open subset

$$
\mathcal{W}(a, b) \subset H^{s}\left(\partial N_{a}, W_{b}\right)
$$

by the condition that for $\gamma \in H^{s}\left(\partial N_{a}, W_{b}\right)$ we have $\gamma \in \mathcal{W}(a, b)$ iff

$$
\gamma\left(x_{i}^{-1}\left(S^{1}\right)\right) \subset W_{i, 1}, \quad \gamma\left(y_{i}^{-1}\left(S^{1}\right)\right) \subset W_{i, 2}
$$

(see 9.1 for the notation $W_{i, 1}$ and $W_{i, 2}$ ) and the curves $\xi_{i} \circ \gamma \circ x_{i}^{-1}$ and $\eta_{i} \circ \gamma \circ y_{i}^{-1}$ from $S^{1}$ to $\mathbb{C} \backslash 0$ both have winding number one about the origin. For $a \in A$ and $b \in B$ let

$$
\begin{aligned}
& \mathcal{U}(a, b):=\left\{\gamma=u \mid \partial N_{a} \in \mathcal{W}(a, b): \begin{array}{l}
u \in \operatorname{Hol}^{s+1 / 2}\left(N_{a}, U_{b}\right), \\
u\left(C_{A} \cap P_{a}\right)=C_{B} \cap Q_{b}
\end{array}\right\}, \\
& \mathcal{V}(a, b):=\left\{\gamma=v \mid \partial N_{a} \in \mathcal{W}(a, b): \begin{array}{l}
v \in \operatorname{Hol}^{s+1 / 2}\left(M_{a}, V_{b}\right) \\
v\left(R_{*} \cap P_{a}\right)=S_{*} \cap Q_{b}
\end{array}\right\} .
\end{aligned}
$$

Here $\operatorname{Hol}^{s+1 / 2}(X, Y)$ is defined by 16 ; holomorphy at a nodal point is defined as in 10.1 Define

$$
\begin{array}{rlrl}
\mathcal{W}_{a}:=\bigsqcup_{b \in B} \mathcal{W}(a, b), & \mathcal{V}_{a}:=\bigsqcup_{b \in B} \mathcal{V}(a, b), & \mathcal{U}_{a}:=\bigsqcup_{b \in B} \mathcal{U}(a, b), \\
\mathcal{W} & :=\bigsqcup_{a \in A} \mathcal{W}_{a}, & \mathcal{V}:=\bigsqcup_{a \in A} \mathcal{V}_{a}, & \mathcal{U}:=\bigsqcup_{a \in A} \mathcal{U}_{a}
\end{array}
$$

Our notation means that the three formulas $(a, \gamma, b) \in \mathcal{W},(\gamma, b) \in \mathcal{W}_{a}$, and $\gamma \in \mathcal{W}(a, b)$ have the same meaning.
11.5. We use the trivialization $\iota: A \times \Gamma \rightarrow \partial N$ in (46) to construct an auxiliary Hilbert manifold structure on $\mathcal{W}$. Define an open set

$$
\mathcal{W}_{0} \subset\left\{(a, \gamma, b) \in A \times H^{s}(\Gamma, W) \times B: \pi_{B} \circ \gamma=b\right\}
$$

by the condition that the map

$$
\begin{equation*}
\mathcal{W}_{0} \rightarrow \mathcal{W}:(a, \gamma, b) \mapsto\left(a, \gamma \circ \iota_{a}^{-1}, b\right) \tag{47}
\end{equation*}
$$

is a bijection. In particular $\gamma\left((i, 1) \times S^{1}\right) \subset W_{i, 1}$ and $\gamma\left((i, 2) \times S^{1}\right) \subset W_{i, 2}$ for $(a, \gamma, b)$ $\in \mathcal{W}_{0}$. By a standard construction $H^{s}(\Gamma, W)$ is a complex Hilbert manifold and the subset
$\left\{(a, \gamma, b): \pi_{B} \circ \gamma=b\right\}$ is a complex Hilbert submanifold of $A \times H^{s}(\Gamma, W) \times B$. This is because the map $H^{s}(\Gamma, W) \rightarrow H^{s}(\Gamma, B)$ induced by $\pi_{B}$ is a holomorphic submersion. Note that $\mathcal{W}_{0}$ is a connected component of $\left\{(a, \gamma, b): \pi_{B} \circ \gamma=b\right\}$ and hence inherits its Hilbert manifold structure. We emphasize that the resulting Hilbert manifold structure on $\mathcal{W}$ depends on the choice of the trivialization. Two different trivializations give rise to a homeomorphism which is of class $C^{k}$ on the dense subset $\mathcal{W} \cap H^{s+k}$.

Definition 11.6. A Hardy trivialization for $\left(\pi_{A}: P \rightarrow A, R_{*}, a_{0}\right)$ is a triple ( $M \cup$ $N, \iota, \rho$ ) where $P=M \cup N$ is a Hardy decomposition with corresponding trivialization $\iota: A \times \Gamma \rightarrow \partial N$ as in 11.2 and

$$
\rho: M \rightarrow \Omega:=M_{a_{0}}
$$

is a trivialization such that

$$
\rho_{a} \circ \iota_{a}=\iota_{a_{0}}, \quad \rho_{a}:=\rho \mid M_{a}: M_{a} \rightarrow \Omega
$$

for $a \in A$ and

$$
\rho\left(R_{*}\right)=R_{*} \cap \Omega=: r_{*} .
$$

We require further that $\rho$ is holomorphic in a neighborhood of the boundary, more precisely that the coordinates $x_{i}$ and $y_{i}$ in Definition 11.2 extend holomorphically to a neighborhood of $N_{i}$ and that $x_{i} \circ \rho=x_{i}$ near $\partial_{1} N_{i}$ and $y_{i} \circ \rho=y_{i}$ near $\partial_{2} N_{i}$.
11.7. The fiber isomorphism $f_{0}: P_{a_{0}} \rightarrow Q_{b_{0}}$ determines a point

$$
\left(a_{0}, \gamma_{0}:=f_{0} \mid \partial N_{a_{0}}, b_{0}\right) \in \mathcal{W} ;
$$

this point lies in $\mathcal{U} \cap \mathcal{V}$ as

$$
\gamma_{0}=u_{0}\left|\partial N_{a_{0}}=v_{0}\right| \partial M_{a_{0}}, \quad \text { where } \quad u_{0}:=f_{0}\left|N_{a_{0}}, v_{0}:=f_{0}\right| M_{a_{0}} .
$$

In the following we will denote neighborhoods of $a_{0}$ in $A$ and $\left(a_{0}, \gamma_{0}, b_{0}\right)$ in $\mathcal{U}, \mathcal{V}$, or $\mathcal{W}$ by the same letters $A$, respectively $\mathcal{U}, \mathcal{V}$, or $\mathcal{W}$, and signal this with the text "shrinking $A$, $\mathcal{U}, \mathcal{V}$, or $\mathcal{W}$ if necessary".

Lemma 11.8. For every $(a, \gamma, b) \in \mathcal{U} \cap \mathcal{V}$ there is a unique fiber isomorphism $f: P_{a} \rightarrow$ $Q_{b}$ with $f \mid \partial N_{a}=\gamma$.

Proof. This follows immediately from Lemma 9.4
Theorem 11.9. Fix an integer $s+1 / 2>4$. After shrinking $A, \mathcal{U}, \mathcal{V}, \mathcal{W}$ if necessary, the following holds.
(i) For each $a \in A, \mathcal{U}_{a}$ and $\mathcal{V}_{a}$ are complex submanifolds of $\mathcal{W}_{a}$.
(ii) $\mathcal{U}$ and $\mathcal{V}$ are complex submanifolds of $\mathcal{W}$.
(iii) The projections $\mathcal{W} \rightarrow A, \mathcal{U} \rightarrow A, \mathcal{V} \rightarrow A$ are holomorphic submersions.
(iv) The unfolding $\left(\pi_{B}, S_{*}, b_{0}\right)$ is infinitesimally universal if and only if

$$
T_{w_{0}} \mathcal{W}_{a_{0}}=T_{w_{0}} \mathcal{U}_{a_{0}} \oplus T_{w_{0}} \mathcal{V}_{a_{0}}, \quad w_{0}=\left(a_{0}, \gamma_{0}, b_{0}\right)
$$

Proof. In 9.1 it was not assumed that $k$ was precisely the number of nodal pairs so the arguments of Section 9 will apply when the central fiber $Q_{b_{0}}$ is replaced by a nearby fiber $Q_{b}$ with possibly fewer nodal points. Hence (i) and (iv) follow from Theorem 9.5 . We prove (ii) and (iii) in four steps.
Step 1. We prove that $\mathcal{U}$ is a complex Hilbert submanifold of $\mathcal{W}$.
The image of the nodal coordinate system $\left(x_{i}, y_{i}, t_{i}\right)$ on $N_{i}$ in $\mathbb{C} \times \mathbb{C} \times \mathbb{C}^{m-1}$ has the form

$$
\left\{(x, y, t) \in \mathbb{D}^{2} \times \mathbb{C}^{m-1}:(x y, t) \in A_{i},|x|<1,|y|<1\right\}
$$

where $A_{i} \subset \mathbb{C} \times \mathbb{C}^{m-1}$ is contained in the open set $\left\{\left|z_{i}\right|<1\right\} \times \mathbb{C}^{m-1}$. The image of the nodal coordinate systems $\left(\xi_{i}, \eta_{i}, \tau_{i}\right)$ on $U_{i}$ in $\mathbb{C} \times \mathbb{C} \times \mathbb{C}^{d-1}$ has the form

$$
\left\{\left(\xi_{i}, \eta_{i}, \tau_{i}\right) \in \mathbb{C} \times \mathbb{C} \times \mathbb{C}^{d-1}:\left|\xi_{i}\right|<2,\left|\eta_{i}\right|<2,\left(\xi_{i} \eta_{i}, \tau_{i}\right) \in B_{i}\right\}
$$

where $B_{i} \subset \mathbb{C} \times \mathbb{C}^{d-1}$ is contained in the open set $\left\{\left|\zeta_{i}\right|<4\right\} \times \mathbb{C}^{d-1}$. By assumption (see 11.4), the fiber isomorphism $f_{0}: P_{0} \rightarrow Q_{0}$ between the fibers over the origin is the identity in these coordinates.

Consider the map

$$
\mathcal{W} \rightarrow A \times\left(H^{s}\right)^{2 k} \times B:(a, \gamma, b) \mapsto\left(a, \alpha_{1}, \beta_{1}, \ldots, \alpha_{k}, \beta_{k}, b\right)
$$

where $\gamma \in \mathcal{W}(a, b)$ and $\alpha_{i}=\xi_{i} \circ \gamma \circ x_{i}^{-1}$ and $\beta_{i}=\eta_{i} \circ \gamma \circ y_{i}^{-1}$. This map is a diffeomorphism from $\mathcal{W}$, with the manifold structure of 11.5 , onto an open subset of the Hilbert manifold $A \times\left(H^{s}\right)^{2 k} \times B$. The image of the subset $\mathcal{U} \subset \mathcal{W}$ under this diffeomorphism consists of all tuples $\left(a, \alpha_{1}, \beta_{1}, \ldots, \alpha_{k}, \beta_{k}, b\right)$ in the image of $\mathcal{W}$ such that

$$
x y=z_{i}(a) \Rightarrow \alpha_{i}(x) \beta_{i}(y)=\zeta_{i}(b) \quad \text { for } i=1, \ldots, k
$$

That this subset is a complex submanifold of $A \times\left(H^{s}\right)^{2 k} \times B$ follows from Theorem 10.4

## Step 2. Define

$$
\mathcal{B}:=\left\{(a, v, b): \begin{array}{l}
a \in A, \quad b \in B, \quad v \in H^{s+1 / 2}\left(M_{a}, V_{b}\right), \\
v\left(R_{*} \cap P_{a}\right)=S_{*} \cap Q_{b}, v \mid \partial N_{a} \in \mathcal{W}(a, b)
\end{array}\right\}
$$

and

$$
\begin{equation*}
\mathcal{Z}:=\left\{(a, v, b) \in \mathcal{B}: v \in \operatorname{Hol}^{s+1 / 2}\left(M_{a}, V_{b}\right)\right\} . \tag{48}
\end{equation*}
$$

We construct an auxiliary Hilbert manifold structure on $\mathcal{B}$ and show that $\mathcal{Z}$ is a smooth submanifold of $\mathcal{B}$.
In analogy with 11.4 define

$$
\mathcal{B}_{0}:=\left\{(a, v, b): \begin{array}{l}
a \in A, \quad b \in B, \quad v \in H^{s+1 / 2}\left(\Omega, V_{b}\right), \\
v\left(r_{*}\right)=S_{*} \cap Q_{b}, v \circ \rho_{a} \mid \partial N_{a} \in \mathcal{W}(a, b)
\end{array}\right\}
$$

where $\Omega:=M_{a_{0}}$ and $r_{*}:=R_{*} \cap \Omega=\rho\left(R_{*}\right)$ as in Definition 11.6. This space is a Hilbert manifold and the Hardy trivialization ( $P=N \cup M, \iota, \rho$ ) induces a bijection

$$
\mathcal{B}_{0} \rightarrow \mathcal{B}:(a, v, b) \mapsto\left(a, v \circ \rho_{a}, b\right)
$$

This defines the Hilbert manifold structure on $\mathcal{B}$. Note the commutative diagram

where the bijection $\mathcal{W}_{0} \rightarrow \mathcal{W}$ is given by (47), the map $\mathcal{B} \rightarrow \mathcal{W}$ is given by restriction to the boundary, and the map $\mathcal{B}_{0} \rightarrow \mathcal{W}_{0}$ is $(a, v, b) \mapsto\left(a, v \circ \iota_{a_{0}}, b\right)$. The bijection $\mathcal{B}_{0} \rightarrow \mathcal{B}$ identifies the subset $\mathcal{Z} \subset \mathcal{B}$ with the subset $\mathcal{Z}_{0} \subset \mathcal{B}_{0}$ given by

$$
\mathcal{Z}_{0}:=\left\{(a, v, b) \in \mathcal{B}_{0}: v \in \operatorname{Hol}^{s+1 / 2}\left(\left(\Omega, j_{a}\right), Q_{b}\right)\right\}
$$

where $j_{a}:=\left(\rho_{a}\right)_{*} J \mid M_{a}, \rho_{a}: M_{a} \rightarrow \Omega$ is the Hardy trivialization, and $J$ is the complex structure on $P$. (Note that the map $a \mapsto j_{a}$ need not be holomorphic.)

We prove that $\mathcal{Z}_{0}$ is a smooth Hilbert submanifold of $\mathcal{B}_{0}$. The tangent space of $\mathcal{B}_{0}$ at a triple $(a, v, b)$ is
$T_{a, v, b} \mathcal{B}_{0}=T_{a} A \times\left\{(\hat{v}, \hat{b}) \in H^{s+1 / 2}\left(\Omega, v^{*} T Q\right) \times T_{b} B: d \pi_{B}(v) \hat{v} \equiv \hat{b}, \hat{v}\left(r_{i}\right) \in T_{v\left(s_{i}\right)} S_{i}\right\}$.
Let $\mathcal{E} \rightarrow \mathcal{B}_{0}$ be the complex Hilbert space bundle whose fiber

$$
\mathcal{E}_{a, v, b}:=H^{s-1 / 2}\left(\Omega, \Lambda_{j_{a}}^{0,1} T^{*} \Omega \otimes v^{*} T Q_{b}\right)
$$

over $(a, v, b) \in \mathcal{B}_{0}$ is the Sobolev space of $(0,1)$-forms on $\left(\Omega, j_{a}\right)$ of class $H^{s-1 / 2}$ with values in the pullback tangent bundle $v^{*} T Q_{b}$. As before the Cauchy-Riemann operator defines a smooth section $\bar{\partial}: \mathcal{B}_{0} \rightarrow \mathcal{E}$ given by

$$
\begin{equation*}
\bar{\partial}(a, v, b):=\bar{\partial}_{j_{a}, J}(v)=\frac{1}{2}\left(d v+J \circ d v \circ j_{a}\right) . \tag{49}
\end{equation*}
$$

Here $J$ denotes the complex structure on $Q$. The zero set of this section is the set $\mathcal{Z}_{0}$ defined above. It follows as in the proof of Theorem 9.5 that the linearized operator $D_{a, v, b}: T_{a, v, b} \mathcal{B}_{0} \rightarrow \mathcal{E}_{a, v, b}$ is surjective and has a right inverse. Hence the zero set $\mathcal{Z}_{0}$ is a smooth Hilbert submanifold of $\mathcal{B}_{0}$.

Step 3. We prove that $\mathcal{V}$ is a complex Hilbert submanifold of $\mathcal{W}$.
As in the proof of Theorem 9.5 restriction to the boundary gives rise to a smooth embedding

$$
\mathcal{Z} \rightarrow \mathcal{W}:(a, v, b) \mapsto(a, \gamma, b), \quad \gamma:=v \mid \partial M_{a},
$$

whose image is $\mathcal{V}$. The only difference in the proof that the restriction map $\mathcal{Z} \rightarrow \mathcal{W}$ is proper is that now we have a $C^{\infty}$ convergent sequence of complex structures on $\Omega$. The proof is otherwise word for word the same. (Note that [16, Theorem B.4.2] allows for a sequence of complex structures on the domain.) Hence $\mathcal{V}$ is a smooth Hilbert submanifold of $\mathcal{W}$.

We prove that $T_{(a, \gamma, b)} \mathcal{V}$ is a complex subspace of $T_{(a, \gamma, b)} \mathcal{W}$ for each triple $(a, \gamma, b)$ $\in \mathcal{V}$. For this we identify $\mathcal{W}$ with $\mathcal{W}_{0}$ and hence $\mathcal{V}$ with the image $\mathcal{V}_{0}$ of the embedding

$$
\begin{equation*}
\mathcal{Z}_{0} \rightarrow \mathcal{W}_{0}:(a, v, b) \mapsto\left(a, v \circ \iota_{a_{0}}, b\right) \tag{50}
\end{equation*}
$$

The tangent space of $\mathcal{B}_{0}$ at a point $(a, v, b)$ is the space of all triples $(\hat{a}, \hat{v}, \hat{b}) \in T_{a} A \times$ $\Omega^{0}\left(\Omega, v^{*} T Q\right) \times T_{b} B$ that satisfy

$$
d \pi(v) \hat{v} \equiv b, \quad \hat{v}\left(r_{i}\right) \in T_{v\left(r_{i}\right)} S_{i}, \quad i=1, \ldots, n
$$

The trivialization $\pi \times \rho: M \rightarrow A \times \Omega$ induces a complex structure of the form (6) on $A \times \Omega$ where $j: A \rightarrow \mathcal{J}(\Omega)$ is a smooth map and $\alpha: T A \rightarrow \operatorname{Vect}(\Sigma)$ a smooth 1form satisfying (7) and (8). Since $\rho$ is holomorphic near $\partial M$ with respect to the complex structure $j\left(a_{0}\right)$ on $\Omega=M_{a_{0}}$ (see Definition 11.6) it follows that $\alpha$ vanishes near $A \times \partial \Omega$. Let $D_{v}: \Omega^{0}\left(\Omega, v^{*} T Q\right) \rightarrow \Omega_{j(a)}^{0,1}\left(\Omega, v^{*} T Q\right)$ denote the linearized Cauchy-Riemann operator associated to a $(j(a), J)$-holomorphic curve $v: \Omega \rightarrow Q$. Then the tangent space of $\mathcal{Z}_{0}$ at $(a, v, b)$ is the kernel of the operator $\mathcal{D}_{a, v}: T_{(a, v, b)} \mathcal{B}_{0} \rightarrow \Omega_{j(a)}^{0,1}\left(\Omega, v^{*} T Q\right)$ given by

$$
\begin{equation*}
\mathcal{D}_{a, v}(\hat{a}, \hat{v}, \hat{b}):=D_{v} \hat{v}+\frac{1}{2} J(v) d v \cdot d j(a) \hat{a} \tag{51}
\end{equation*}
$$

It follows from (15) with $\sigma_{i}(a) \equiv r_{i}$ that the vector field $\alpha(a, \hat{a})$ vanishes at the point $r_{i}$ for every $a \in A$ and every $\hat{a} \in T_{a} A$. Hence the tangent space $T_{(a, v, b)} \mathcal{B}_{0}$ carries a complex structure

$$
\mathcal{I}(a, v, b)(\hat{a}, \hat{v}, \hat{b}):=(\sqrt{-1} \hat{a}, J(v) \hat{v}-d v \cdot \alpha(a, \hat{a}), \sqrt{-1} \hat{b})
$$

and, by direct calculation using (8), we find

$$
J(v) \circ \mathcal{D}_{a, v}=\mathcal{D}_{a, v} \circ \mathcal{I}(a, v, b)
$$

Hence the (almost) complex structure $\mathcal{I}$ descends to $\mathcal{Z}_{0}$. Since $\alpha$ vanishes near the boundary the differential of the embedding 50 is complex-linear and hence $\mathcal{V}_{0}$ is a complex submanifold of $\mathcal{W}_{0}$ as claimed.

Step 4. We prove (iii).
That the projections $\mathcal{W} \rightarrow A, \mathcal{U} \rightarrow A, \mathcal{V} \rightarrow A$ are holomorphic is obvious from the construction. We prove that these three maps are submersions. For the map $\mathcal{U} \rightarrow A$, and hence for $\mathcal{W} \rightarrow A$, this follows immediately from Proposition 10.9 For $\mathcal{V}$ observe that the linearized operator of the section (49) is the operator (51). Choose $\hat{a} \in T_{a} A$ and solve the equation $\mathcal{D}_{a, v}(\hat{a}, \hat{v}, 0)=0$ for $\hat{v}$. This equation has a solution because $D_{v}$ is surjective with domain the space of vertical vector fields that vanish at the points $r_{i}$ and target the space of vertical ( 0,1 )-forms. This proves (iii).

## 12. Proofs of the main theorems

Definition 12.1. The set $C$ of critical points of a nodal family $\pi: Q \rightarrow B$ is a submanifold of $Q$ and the restriction of $\pi$ to this set is an immersion. The family is said to be regular nodal at $b \in B$ if all self-intersections of $\pi(C)$ in $\pi^{-1}(b)$ are transverse, i.e.

$$
\operatorname{dim}_{\mathbb{C}}\left(\operatorname{im} d \pi\left(q_{1}\right) \cap \cdots \cap \operatorname{im} d \pi\left(q_{m}\right)\right)=\operatorname{dim}_{\mathbb{C}}(B)-m
$$

whenever $q_{1}, \ldots, q_{m} \in C$ are pairwise distinct and $\pi\left(q_{1}\right)=\cdots=\pi\left(q_{m}\right)=b$; the nodal family is called regular nodal if it regular nodal at each $b \in B$.

Lemma 12.2. Let u be a desingularization of the fiber $Q_{b}, g$ be the arithmetic genus of the fiber, and $n$ be the number of marked points. Then the following hold:
(i) $D_{u, b}(\hat{u}, \hat{b}) \in \mathcal{Y}_{u}$ for $(\hat{u}, \hat{b}) \in \mathcal{X}_{u, b}$.
(ii) The operator $D_{u, b}: \mathcal{X}_{u, b} \rightarrow \mathcal{Y}_{u}$ is Fredholm.
(iii) The Fredholm index satisfies

$$
\operatorname{index}_{\mathbb{C}}\left(D_{u, b}\right) \geq 3-3 g-n+\operatorname{dim}_{\mathbb{C}}(B)
$$

with equality if and only if $\pi$ is regular nodal at $b$.
Proof. We prove (i). Choose $(\hat{u}, \hat{b}) \in \mathcal{X}_{u, b}$ and let

$$
\bar{\partial}: \Omega^{0}\left(\Sigma, T_{b} B\right) \rightarrow \Omega^{0,1}\left(\Sigma, T_{b} B\right)
$$

denote the usual Cauchy-Riemann operator. Then $d \pi_{B}(u) D_{u} \hat{u}=\bar{\partial} d \pi_{B}(u) \hat{u}=0$ since $d \pi_{B}(u) \hat{u}$ is a constant vector. Hence $D_{u} \hat{u} \in \mathcal{Y}_{u}$. Item (ii) is immediate as $D_{u}$ is Fredholm as a map from vertical vector fields to vertical $(0,1)$-forms and $D_{u, b}$ is obtained from $D_{u}$ by a finite-dimensional modification of the domain. (A vertical vector field is an element $\hat{u} \in \Omega^{0}\left(\Sigma, u^{*} T Q\right)$ such that $d \pi(u) \hat{u}=0$; a vertical ( 0,1 )-form is an element $\eta \in$ $\Omega^{0,1}\left(\Sigma, u^{*} T Q\right)$ such that $d \pi(u) \eta=0$, i.e. an element of $\mathcal{Y}_{u}$.)

We prove (iii). The arithmetic genus $g$ of the fiber is given by

$$
\begin{equation*}
g=\text { \#edges }- \text { \#vertices }+1+\sum_{i} g_{i} \tag{52}
\end{equation*}
$$

where \#vertices $=\sum_{i} 1$ is the number of components of $\Sigma$, \#edges is the number of pairs of nodal points, and $g_{i}$ is the genus of the $i$ th component. Now consider the subspace

$$
\mathcal{X}_{u}:=\left\{(\hat{u}, \hat{b}) \in \mathcal{X}_{u, b}: \hat{b}=0\right\}
$$

of all vertical vector fields along $u$ satisfying the nodal and marked point conditions. If $(\hat{u}, \hat{b}) \in \mathcal{X}_{u, b}$, then the vector $\hat{b}$ belongs to the image of $d \pi(q)$ for every $q \in Q_{b}$. Hence the codimension of $\mathcal{X}_{u}$ in $\mathcal{X}_{u, b}$ is

$$
\operatorname{codim}_{\mathcal{X}_{u, b}}\left(\mathcal{X}_{u}\right)=\operatorname{dim}\left(\bigcap_{q \in Q_{b}} \operatorname{im} d \pi(q)\right) \geq \operatorname{dim}_{\mathbb{C}}(B)-\text { \#edges }
$$

with equality if and only if $\pi_{B}$ is regular nodal at $b$. By Riemann-Roch the restricted operator has Fredholm index

$$
\operatorname{index}_{\mathbb{C}}\left(D_{u}: \mathcal{X}_{u} \rightarrow \mathcal{Y}_{u}\right)=\sum_{i}\left(3-3 g_{i}\right)-2 \# \text { edges }-n
$$

Here the summand -2 \#edges arises from the nodal point conditions in the definition of $\mathcal{X}_{u}$. To obtain the Fredholm index of $D_{u, b}$ we must add the codimension of $\mathcal{X}_{u}$ in $\mathcal{X}_{u, b}$ to the last identity. Hence

$$
\begin{aligned}
\operatorname{index}_{\mathbb{C}}\left(D_{u, b}\right) & \geq \sum_{i}\left(3-3 g_{i}\right)-3 \text { \#edges }-n+\operatorname{dim}_{\mathbb{C}}(B) \\
& =3-3 g-n+\operatorname{dim}_{\mathbb{C}}(B) .
\end{aligned}
$$

The last identity follows from (52). Again, equality holds if and only if $\pi_{B}$ is regular nodal at $b$.

Proof of Theorem 5.3. The proof is an easy application of the openness of transversality. Take $P=Q, A=B, \pi_{A}=\pi_{B}$, and $f_{0}=$ id, so $\gamma_{0}$ is the inclusion of $\partial N_{b_{0}}$ in $Q_{b_{0}}$. Assume the unfolding ( $\pi_{B}: Q \rightarrow B, S_{*}, b_{0}$ ) is infinitesimally universal. Choose $b \in B$ near $b_{0}$, fix an integer $s+1 / 2>4$, and let $\mathcal{U}_{b}$ and $\mathcal{V}_{b}$ be the manifolds in 11.4 with $P=Q$ and $a=b$. To show that $\left(\pi_{B}, S_{*}, b\right)$ is infinitesimally universal we must show that $\mathcal{U}_{b}$ and $\mathcal{V}_{b}$ intersect transversally at $\gamma$ where $\gamma$ is the inclusion of $\partial N_{b}$ in $Q_{b}$. Since $b$ is near $b_{0}$, so also is $\gamma$ near $\gamma_{0}$. Consider the three subspaces $T_{\gamma} \mathcal{W}_{b}, T_{\gamma} \mathcal{U}_{b}, T_{\gamma} \mathcal{V}_{b}$, of $T_{\gamma} \mathcal{W}$. We have $T_{\gamma} \mathcal{U}_{b}=T_{\gamma} \mathcal{W}_{b} \cap T_{\gamma} \mathcal{U}$ and the intersection is transverse as the projection $\mathcal{U} \rightarrow B$ is a submersion. Similarly, $T_{\gamma} \mathcal{V}_{b}=T_{\gamma} \mathcal{W}_{b} \cap T_{\gamma} \mathcal{V}$. Hence the subspaces $T_{\gamma} \mathcal{U}_{b}$ and $T_{\gamma} \mathcal{V}_{b}$ depend continuously on $(b, \gamma)$. By Theorem 11.9 (iv) the submanifolds $\mathcal{U}_{b_{0}}$ and $\mathcal{V}_{b_{0}}$ intersect transversally at $\gamma_{0}$, i.e. $T_{\gamma_{0}} \mathcal{W}_{b_{0}}=T_{\gamma_{0}} \mathcal{U}_{b_{0}}+T_{\gamma_{0}} \mathcal{V}_{b_{0}}$. Hence $T_{\gamma} \mathcal{W}_{b}=T_{\gamma} \mathcal{U}_{b}+T_{\gamma} \mathcal{V}_{b}$ for $(b, \gamma)$ near $\left(b_{0}, \gamma_{0}\right)$. Hence the unfolding $\left(\pi_{B}, S_{*}, b\right)$ is infinitesimally universal for $b$ near $b_{0}$ by Theorem 11.9 again as required.
Proof of Theorem 5.4. We proved "only if" in Section 5. For "if" assume that the unfolding $\left(\pi_{B}, S_{*}, b_{0}\right)$ is infinitesimally universal. Let $\left(\pi_{A}, R_{*}, a_{0}\right)$ be another unfolding and $f_{0}: P_{a_{0}} \rightarrow Q_{b_{0}}$ be a fiber isomorphism. Assume the notation introduced in Section 11 In particular assume the hypotheses of Theorem 11.9 .

Step 1. $\mathcal{U}$ and $\mathcal{V}$ intersect transversally at $\left(a_{0}, \gamma_{0}, b_{0}\right)$.
Abbreviate $w_{0}:=\left(a_{0}, \gamma_{0}, b_{0}\right)$. Choose $\hat{w} \in T_{w_{0}} \mathcal{W}$ and let $\hat{a}=d \pi\left(w_{0}\right) \hat{w}$. As the restriction of $\pi$ to $\mathcal{U}$ is a submersion there is a vector $\hat{u} \in T_{w_{0}} \mathcal{U}$ with $d \pi\left(w_{0}\right) \hat{u}=\hat{a}$. Then $\hat{w}-\hat{u} \in T_{w_{0}} \mathcal{W}_{a_{0}}$ so by Theorem 11.9 (iv) there are vectors $\hat{u}_{0} \in T_{w_{0}} \mathcal{U}_{a_{0}}$ and $\hat{v}_{0} \in T_{w_{0}} \mathcal{V}_{a_{0}}$ with $\hat{w}-\hat{u}=\hat{u}_{0}+\hat{v}_{0}$.
Step 2. The projection $\mathcal{U} \cap \mathcal{V} \rightarrow A$ is a holomorphic diffeomorphism.
By Step 1 the intersection $\mathcal{U} \cap \mathcal{V}$ is a complex submanifold of $\mathcal{W}$ (after shrinking) and $T_{w}(\mathcal{U} \cap \mathcal{V})=T_{w} \mathcal{U} \cap T_{w} \mathcal{V}$ for $w \in \mathcal{U} \cap \mathcal{V}$. By the inverse function theorem it is enough to show that $d \pi\left(w_{0}\right): T_{w_{0}}(\mathcal{U} \cap \mathcal{V}) \rightarrow T_{a_{0}} A$ is bijective. Injectivity follows from Theorem 11.9 (iv) and the fact that $T_{w_{0}} \mathcal{U}_{a_{0}}=T_{w_{0}} \mathcal{U} \cap \operatorname{ker} d \pi\left(w_{0}\right)$ and $T_{w_{0}} \mathcal{V}_{a_{0}}=T_{w_{0}} \mathcal{V} \cap$ $\operatorname{ker} d \pi\left(w_{0}\right)$. We prove surjectivity. Choose $\hat{a} \in T_{a_{0}} A$. Since the restrictions of $\pi$ to $\mathcal{U}$ and $\mathcal{V}$ are submersions, there exist $\hat{u} \in T_{w_{0}} \mathcal{U}$ and $\hat{v} \in T_{w_{0}} \mathcal{V}$ with $d \pi\left(w_{0}\right) \hat{u}=d \pi\left(w_{0}\right) \hat{v}=\hat{a}$. The difference $\hat{u}-\hat{v}$ lies in $T_{w_{0}} \mathcal{W}_{a_{0}}$ so, by Theorem 11.9 (iv), there are $\hat{u}_{0} \in T_{w_{0}} \mathcal{U}_{a_{0}}$ and $\hat{v}_{0} \in T_{w_{0}} \mathcal{V}_{a_{0}}$ with $\hat{u}-\hat{v}=\hat{u}_{0}+\hat{v}_{0}$. Hence $\hat{u}-\hat{u}_{0}=\hat{v}+\hat{v}_{0}$ lies in $T_{w_{0}}(\mathcal{U} \cap \mathcal{V})$ and projects to $\hat{a}$.

Now define $\Phi: P \rightarrow Q$ and $\phi: A \rightarrow B$ by $\phi(a):=b_{a}$ and $\Phi \mid P_{a}:=f_{a}$, where $f_{a}: P_{a} \rightarrow Q_{b_{a}}$ is the unique fiber isomorphism that satisfies $f_{a} \mid \partial N_{a}=\gamma_{a}$. (See Lemma 11.8)

Step 3. The maps $\phi$ and $\Phi$ and holomorphic.
The map $\phi$ is the composition of the inverse of the projection $\mathcal{U} \cap \mathcal{V} \rightarrow A$ with the projection $\mathcal{U} \cap \mathcal{V} \rightarrow B$ and is therefore holomorphic by Step 2. By Lemma 10.18 the
restriction of $\Phi$ to $\operatorname{int}(N)$ is holomorphic and hence smooth. To prove that the restriction of $\Phi$ to $\operatorname{int}(M)$ is holomorphic we write it as the composition

$$
\operatorname{int}(M) \rightarrow A \times \Omega \rightarrow(\mathcal{U} \cap \mathcal{V}) \times \Omega \rightarrow \mathcal{Z}_{0} \times \Omega \rightarrow Q
$$

where the first map is the product $\pi_{A} \times \rho$, the second map is the inverse of the projection $\mathcal{U} \cap \mathcal{V} \rightarrow A$ on the first factor, the third map is given by the obvious embedding of $\mathcal{U} \cap \mathcal{V}$ into $\mathcal{V}_{0} \cong \mathcal{Z}_{0}$, and the fourth map is the evaluation map $(a, v, b, z) \mapsto v(z)$. All five spaces are complex manifolds. In particular, the complex structure on $\mathcal{Z}_{0} \times \Omega$ is

$$
(\hat{a}, \hat{v}, \hat{b}, \hat{z}) \mapsto(\sqrt{-1} \hat{a}, J(v) \hat{v}-d v \cdot \alpha(a, \hat{a}), \sqrt{-1} \hat{b}, j(a)(z) \hat{z}+\alpha(a, \hat{a})(z)) .
$$

All four maps are holomorphic and hence, so is the restriction of $\Phi$ to $\operatorname{int}(M)$. Thus we have proved that $\Phi$ is holomorphic on $P \backslash \partial N$. Since $\Phi$ is continuous, it follows that $\Phi$ is holomorphic everywhere. This proves the theorem.

Proof of Theorem 5.5 Assume that the unfolding ( $\pi_{B}, S_{*}, b_{0}$ ) is infinitesimally universal and let $(\phi, \Phi)$ is a pseudomorphism from $\left(\pi_{A}, R_{*}, a_{0}\right)$ to $\left(\pi_{B}, S_{*}, b_{0}\right)$. Then, in the notation of the proof of Theorem $5.4\left(\gamma_{a}, b_{a}\right):=\left(\Phi \mid \partial N_{a}, \phi(a)\right)$ is the unique intersection point of $\mathcal{U}_{a}$ and $\mathcal{V}_{a}$. Hence $(\phi, \Phi)$ agrees with the unique (holomorphic) morphism constructed in the proof of Theorem 5.4
Proof of Theorem 5.6. We proved "only if" in Section 5 For "if" assume that ( $\Sigma, s_{*}, v, j$ ) is stable. We first consider the case where $\Sigma$ is disconnected and there are no nodal points. Let $\Sigma_{1}, \ldots, \Sigma_{k}$ be the components of $\Sigma, g_{j}$ be the genus of $\Sigma_{j}$, and $n_{j}$ be the number of marked points on $\Sigma_{j}$. Let $I_{j} \subset\{1, \ldots, n\}$ be the index set associated to the marked points in $\Sigma_{j}$. Then $\{1, \ldots, n\}$ is the disjoint union of the sets $I_{1}, \ldots, I_{k}$ and $n_{j}=\left|I_{j}\right|>$ $2-2 g_{j}$. By Theorem 8.9 there exists, for each $j$, a universal unfolding $\left(\pi_{j}: Q_{j} \rightarrow\right.$ $\left.B_{j},\left\{S_{j i}\right\}_{i \in I_{j}}, b_{0 j}, v_{0 j}\right)$ of $\Sigma_{j}$. Note that $\operatorname{dim}_{\mathbb{C}}\left(B_{j}\right)=3 g_{j}-3+n_{j}$. Define

$$
\begin{gathered}
B_{0}:=B_{1} \times \cdots \times B_{k}, \\
Q_{0}:=\bigsqcup_{j=1}^{k} B_{1} \times \cdots \times B_{j-1} \times Q_{j} \times B_{j+1} \times \cdots \times B_{k}, \\
\pi_{0}\left(b_{1}, \ldots, b_{j-1}, q_{j}, b_{j+1}, \ldots, b_{k}\right):=\left(b_{1}, \ldots, b_{j-1}, \pi_{j}\left(q_{j}\right), b_{j+1}, \ldots, b_{k}\right), \\
S_{0 i}:=\left\{\left(b_{1}, \ldots, b_{j-1}, q_{j}, b_{j+1}, \ldots, b_{k}\right): q_{j} \in S_{i j}\right\}, \quad i \in I_{j}, \\
b_{0}:=\left(b_{01}, \ldots, b_{0 k}\right), \\
v_{0}(z):=\left(b_{01}, \ldots, b_{0, j-1}, v_{0 j}(z), b_{0, j+1}, \ldots, b_{0 k}\right), \quad z \in \Sigma_{j} .
\end{gathered}
$$

Then the quadruple $\left(\pi_{0}, S_{0 *}, b_{0}, v_{0}\right)$ is a universal unfolding of $\Sigma$.
Next consider the general case. Denote the nodal points on $\Sigma$ by $v=\left\{\left\{r_{1}, s_{1}\right\}, \ldots\right.$, $\left.\left\{r_{m}, s_{m}\right\}\right\}$ and the marked points by $t_{1}, \ldots, t_{n}$. Assume, without loss of generality, that the signature of ( $\Sigma, t_{*}, v, j$ ) is a connected graph (see Definition 3.4). Replace all the nodal points by marked points. Then, by what we have just proved, there exists a universal unfolding ( $\pi_{0}, R_{0 *}, S_{0 *}, T_{0 *}, b_{0}, v_{0}$ ) of ( $\Sigma, r_{*}, s_{*}, t_{*}, j$ ). Choose disjoint open sets $U_{1}, \ldots, U_{m}, V_{1}, \ldots, V_{m} \subset Q_{0}$ such that

$$
R_{0 i} \subset U_{i}, \quad S_{0 i} \subset V_{i}, \quad U_{i} \cap T_{0 j}=V_{i} \cap T_{0 j}=\emptyset
$$

for $i=1, \ldots, m$ and $j=1, \ldots, n$. Choose holomorphic functions $x_{i}: U_{i} \rightarrow \mathbb{C}$ and $y_{i}: V_{i} \rightarrow \mathbb{C}$ such that

$$
x_{i}\left(R_{0 i}\right)=0, \quad y_{i}\left(S_{0 i}\right)=0
$$

and $\left(\pi_{0}, x_{i}\right)$ and $\left(\pi_{0}, y_{i}\right)$ are coordinates on $Q_{0}$. Shrink $B$ and the open sets $U_{i}, V_{i}$ if necessary. Assume without loss of generality that $x_{i}\left(U_{i}\right)=y_{i}\left(V_{i}\right)=\mathbb{D}$. Define

$$
B:=B_{0} \times \mathbb{D}^{m}, \quad Q:=Q_{0} \times \mathbb{D}^{m} / \sim
$$

Two points $(q, z)$ and $\left(q^{\prime}, z\right)$ with $q \in U_{i}$ and $q^{\prime} \in V_{i}$ are identified if and only if $\pi_{0}(q)=\pi_{0}\left(q^{\prime}\right)$ and either

$$
x_{i}(q) y_{i}\left(q^{\prime}\right)=z_{i} \neq 0 \quad \text { or } \quad x_{i}(q)=y_{i}\left(q^{\prime}\right)=z_{i}=0
$$

The equivalence relation on $Q_{0} \times \mathbb{D}^{m}$ is generated by these identifications. (Two points $(q, z)$ and $\left(q^{\prime}, z\right)$ with $\pi_{0}(q)=\pi_{0}\left(q^{\prime}\right), q \in U_{i}, q^{\prime} \in V_{i}, z_{i}=0$ are not identified in the case $x_{i}(q)=0$ and $y_{i}\left(q^{\prime}\right) \neq 0$ nor in the case $x_{i}(q) \neq 0$ and $y_{i}\left(q^{\prime}\right)=0$.) The projection $\pi: Q \rightarrow B$ and the sections $T_{j}: B \rightarrow Q$ are defined by

$$
\pi([q, z]):=\left(\pi_{0}(q), z\right), \quad T_{j}:=\left\{[q, z]: q \in T_{0 j}\right\}
$$

for $j=1, \ldots, n$.
We have thus defined $Q$ as a set. The manifold structure is defined as follows. For $i \in\{1, \ldots, m\}$ denote by $C_{i} \subset Q$ the set of all equivalence classes $[q, z] \in Q$ that satisfy $z_{i}=0$ and $q \in R_{0 i}$. Note that any such point is equivalent to the pair $\left[q^{\prime}, z\right]$ with $q^{\prime} \in S_{0 i}$ and $\pi_{0}\left(q^{\prime}\right)=\pi_{0}(q)$. Let

$$
C:=\bigcup_{i=1}^{m} C_{i}
$$

The manifold structure on $Q \backslash C$ is induced by the product manifold structure on $Q_{0} \times \mathbb{D}^{m}$. We now explain the manifold structure near $C_{i}$. Fix a constant $0<\varepsilon<1$ and define an open neighborhood $N_{i} \subset Q$ of $C_{i}$ by

$$
\begin{aligned}
N_{i}:= & C_{i} \cup\left\{[q, z] \in Q: q \in U_{i},\left|z_{i}\right| / \varepsilon<\left|x_{i}(q)\right|<\varepsilon\right\} \\
& \cup\left\{[q, z] \in Q: q \in V_{i},\left|z_{i}\right| / \varepsilon<\left|y_{i}(q)\right|<\varepsilon\right\} .
\end{aligned}
$$

A coordinate chart on $N_{i}$ is the map

$$
[q, z] \mapsto\left(b_{0}, z_{1}, \ldots, z_{i-1}, x_{i}, y_{i}, z_{i+1}, \ldots, z_{m}\right)
$$

where $b_{0}:=\pi_{0}(q) \in B_{0}$,

$$
x_{i}:= \begin{cases}x_{i}(q) & \text { if } q \in U_{i} \\ z_{i} / y_{i}(q) & \text { if } q \in V_{i}, z_{i} \neq 0 \\ 0 & \text { if } q \in V_{i}, z_{i}=0\end{cases}
$$

(if $[q, z] \in N_{i}$ and $q \in V_{i}$ then $z_{i} \neq 0$ implies $y_{i}(q) \neq 0$ ), and

$$
y_{i}:= \begin{cases}y_{i}(q) & \text { if } q \in V_{i}, \\ z_{i} / x_{i}(q) & \text { if } q \in U_{i}, z_{i} \neq 0 \\ 0 & \text { if } q \in U_{i}, z_{i}=0\end{cases}
$$

With this construction the transition maps are holomorphic and so $Q$ is a complex manifold. In the coordinate chart on $N_{i}$ the projection $\pi$ has the form

$$
\left(b_{0}, z_{1}, \ldots, z_{i-1}, x_{i}, y_{i}, z_{i+1}, \ldots, z_{m}\right) \mapsto\left(b_{0}, z\right), \quad z_{i}:=x_{i} y_{i}
$$

It follows that $\pi$ is holomorphic, the critical set of $\pi$ is $C$, and each critical point is nodal. Moreover, $\pi$ restricts to a diffeomorphism from $C_{i}$ onto the submanifold $\left\{z_{i}=0\right\} \subset B$. Hence $\pi$ is a regular nodal family (see Definition 12.1).

Write $b:=\left(b_{0}, 0\right) \in B$, let $\iota: Q_{0} \rightarrow Q$ be the holomorphic map defined by $\iota(q):=$ [ $q, 0$ ], and define $v: \Sigma \rightarrow Q$ by $v:=\iota \circ v_{0}$. Then $v$ is a desingularization of the fiber $Q_{b}=\pi^{-1}(b)$.

We prove that the triple $\left(\pi, T_{*}, b\right)$ is a universal unfolding. Since the signature of the marked nodal Riemann surface $\Sigma$ is a connected graph, the first Betti number of this graph is $1-k+m$ (since $m$ is the number of edges, i.e. of equivalent pairs of nodal points, and $k$ is the number of vertices, i.e. of components of $\Sigma$ ). Hence the arithmetic genus $g$ (see Definition 3.6) of the central fiber $Q_{b}$ is given by

$$
g-1=m+\sum_{j=1}^{k}\left(g_{j}-1\right) .
$$

Now recall that $n_{j}$ is the number of special points on $\Sigma_{j}$ and

$$
\sum_{j=1}^{k} n_{j}=n+2 m
$$

Since $\operatorname{dim}_{\mathbb{C}}\left(B_{j}\right)=3 g_{j}-3+n_{j}$ this implies

$$
\operatorname{dim}_{\mathbb{C}}(B)=\operatorname{dim}_{\mathbb{C}}\left(B_{0}\right)+m=\sum_{j=1}^{k}\left(3 g_{j}-3+n_{j}\right)+m=3 g-3+n
$$

Since the Riemann family $\pi: Q \rightarrow B$ is regular nodal it follows from Lemma 12.2 that the operator $D_{v, b}$ (see Definition 5.2 has Fredholm index zero. Hence $D_{v, b}$ is bijective if and only if it is injective.

We prove in three steps that $D_{v, b}$ is injective. First, every vector $(\hat{v}, \hat{b}) \in \mathcal{X}_{v, b}$ with $\hat{b}=:\left(\hat{b}_{0}, \hat{z}\right)$ satisfies $\hat{z}=0$. To see this note that $d \pi(v) \hat{v} \equiv \hat{b}$. For every $i$ there is a unique pair of equivalent nodal points in $\Sigma$ that are mapped to $C_{i}$ under $v$. Since the image of $d \pi$ at each point in $C_{i}$ is contained in the subspace $\left\{\hat{z}_{i}=0\right\}$ it follows that $\hat{z}=0$. Second, we define a linear operator

$$
\mathcal{X}_{v_{0}, b_{0}} \rightarrow X_{v, b}:\left(\hat{v}_{0}, \hat{b}_{0}\right) \mapsto(\hat{v}, \hat{b})
$$

by

$$
\hat{b}:=\left(\hat{b}_{0}, 0\right), \quad \hat{v}(s):=\left(\hat{v}_{0}(s), 0\right) \in T_{v(s)} Q
$$

for $s \in \Sigma \backslash\left\{r_{1}, \ldots, r_{m}, s_{1}, \ldots, s_{m}\right\}$. Then $\hat{v}$ extends uniquely to a smooth vector field along $v$. In the above coordinates on $N_{i}$ the tangent vector $\hat{v}\left(r_{i}\right)=\hat{v}\left(s_{i}\right) \in T_{v\left(r_{i}\right)} Q=$ $T_{v\left(s_{i}\right)} Q$ has the form ( $\hat{x}_{i}, \hat{y}_{i}, \hat{b}_{0}, 0$ ), where

$$
\hat{x}_{i}:=d x_{i}\left(v_{0}\left(r_{i}\right)\right) \hat{v}_{0}\left(r_{i}\right) \quad \text { and } \quad \hat{y}_{i}:=d y_{i}\left(v_{0}\left(s_{i}\right)\right) \hat{v}_{0}\left(s_{i}\right) .
$$

It is easy to see that this operator is bijective. Third, since the map $\iota: Q_{0} \rightarrow Q$ is holomorphic, it follows that

$$
D_{v, b}(\hat{v}, \hat{b})=d \iota(v) D_{v_{0}, b_{0}}\left(\hat{v}_{0}, \hat{b}_{0}\right)
$$

Hence the operator $\mathcal{X}_{v_{0}, b_{0}} \rightarrow X_{v, b}$ restricts to a vector space isomorphism from the kernel of $D_{v_{0}, b_{0}}$ to the kernel of $D_{v, b}$. By construction, the operator $D_{v_{0}, b_{0}}$ is injective and hence, so is $D_{v, b}$. Thus we have proved that $D_{v, b}$ is bijective. Hence, by Theorem 5.4 the quadruple $\left(\pi, T_{*}, b, v\right)$ is a universal unfolding of $\left(\Sigma, s_{*}, v, j\right)$.

## 13. Topology

The orbit space of a groupoid inherits a topology from an orbifold structure on the groupoid. This topology is independent of the choice of the structure in the sense that equivalent orbifold structures determine the same topology (see Section 2). In the case of the Deligne-Mumford orbifold $\overline{\mathcal{M}}_{g, n}$, the topology has as a basis for the open sets the collection of all sets $\left\{\left[\Sigma_{b}\right]_{\mathcal{B}}: b \in U\right\}$ where $\left(\pi_{B}: Q \rightarrow B, S_{*}\right)$ is a universal family as in Definition6.2, the functor

$$
B \rightarrow \overline{\mathcal{B}}_{g, n}: b \mapsto \Sigma_{b}
$$

is the corresponding orbifold structure as in Definition 6.4, and $U$ runs over all open subsets of $B$. In Section 14 we show that $\overline{\mathcal{M}}_{g, n}$ is compact and Hausdorff. (See Example 2.8 for an example which shows why it is not obvious that the moduli space is Hausdorff.) For this purpose we introduce in this section a notion of convergence of sequences of marked nodal Riemann surfaces which we call DM-convergence.
13.1. Let $\Sigma$ be a compact oriented surface and $\gamma \subset \Sigma$ be a disjoint union of embedded circles. We denote by $\Sigma_{\gamma}$ the compact surface with boundary which results by cutting open $\Sigma$ along $\gamma$. This implies that there is a local embedding

$$
\sigma: \Sigma_{\gamma} \rightarrow \Sigma
$$

which maps $\operatorname{int}\left(\Sigma_{\gamma}\right)$ one-to-one onto $\Sigma \backslash \gamma$ and maps $\partial \Sigma_{\gamma}$ two-to-one onto $\gamma$. One might call $\sigma$ the suture map and $\gamma$ the incision.

Definition 13.2. Let $\left(\Sigma^{\prime}, \nu^{\prime}\right)$ and $(\Sigma, \nu)$ be nodal surfaces. A smooth map $\phi: \Sigma^{\prime} \backslash \gamma^{\prime} \rightarrow$ $\Sigma$ is called a $\left(v^{\prime}, v\right)$-deformation iff $\gamma^{\prime} \subset \Sigma^{\prime} \backslash \bigcup v^{\prime}$ is a disjoint union of embedded circles such that (where $\sigma: \Sigma_{\gamma^{\prime}}^{\prime} \rightarrow \Sigma^{\prime}$ is the suture map just defined) we have

- $\phi_{*} \nu^{\prime}:=\left\{\left\{\phi\left(y_{1}^{\prime}\right), \phi\left(y_{2}^{\prime}\right)\right\}:\left\{y_{1}^{\prime}, y_{2}^{\prime}\right\} \in \nu^{\prime}\right\} \subset v$.
- $\phi$ is a diffeomorphism from $\Sigma^{\prime} \backslash \gamma^{\prime}$ onto $\Sigma \backslash \gamma$, where $\gamma:=\bigcup\left(v \backslash \phi_{*} \nu^{\prime}\right)$.
- $\phi \circ \sigma \mid \operatorname{int}\left(\Sigma_{\gamma^{\prime}}^{\prime}\right)$ extends to a continuous surjective map $\Sigma_{\gamma^{\prime}}^{\prime} \rightarrow \Sigma$ such that the preimage of each nodal point in $\gamma$ is a component of $\partial \Sigma_{\gamma^{\prime}}^{\prime}$ and two boundary components which map under $\sigma$ to the same component of $\gamma^{\prime}$ map to a nodal pair $\{x, y\} \in \gamma$.

A sequence $\phi_{k}:\left(\Sigma_{k} \backslash \gamma_{k}, \nu_{k}\right) \rightarrow(\Sigma, v)$ of $\left(v_{k}, v\right)$-deformations is called monotypic iff $\left(\phi_{k}\right)_{*} \nu_{k}$ is independent of $k$.

Definition 13.3. A sequence $\left(\Sigma_{k}, s_{k, *}, \nu_{k}, j_{k}\right)$ of marked nodal Riemann surfaces of type ( $g, n$ ) is said to converge monotypically to a marked nodal Riemann surface ( $\Sigma, s_{*}, \nu, j$ ) of type $(g, n)$ iff there is a monotypic sequence $\phi_{k}: \Sigma_{k} \backslash \gamma_{k} \rightarrow \Sigma$ of $\left(v_{k}, \nu\right)$-deformations such that for $i=1, \ldots, n$ the sequence $\phi_{k}\left(s_{k, i}\right)$ converges to $s_{i}$ in $\Sigma$, and the sequence $\left(\phi_{k}\right)_{*} j_{k}$ of complex structures on $\Sigma \backslash \gamma$ converges to $j \mid(\Sigma \backslash \gamma)$ in the $C^{\infty}$ topology. The sequence $\left(\Sigma_{k}, s_{k, *}, v_{k}, j_{k}\right)$ is said to DM-converge to ( $\Sigma, j, s, v$ ) iff, after discarding finitely many terms, it is the disjoint union of finitely many sequences which converge monotypically to $(\Sigma, s, v, j)$.

Remark 13.4. Assume that $\left(\Sigma_{k}, s_{k, *}, \nu_{k}, j_{k}\right)$ DM-converges to $\left(\Sigma, s_{*}, v, j\right)$, that ( $\Sigma_{k}, s_{k, *}, v_{k}, j_{k}$ ) is isomorphic to ( $\Sigma_{k}^{\prime}, s_{k, *}^{\prime}, v_{k}^{\prime}, j_{k}^{\prime}$ ), and that ( $\Sigma, s_{*}, v, j$ ) is isomorphic to $\left(\Sigma^{\prime}, s_{*}^{\prime}, v^{\prime}, j^{\prime}\right)$. Then $\left(\Sigma_{k}^{\prime}, s_{k, *}^{\prime}, v_{k}^{\prime}, j_{k}^{\prime}\right)$ DM-converges to ( $\Sigma^{\prime}, s_{*}^{\prime}, \nu^{\prime}, j^{\prime}$ ).

Remark 13.5. Our definition of deformation agrees with [10, p. 79]. Our definition of monotypic convergence is Hummel's definition of weak convergence to cusp curves in [10, p. 80] (with the target manifold $M$ a point) except that he does not allow marked points. However, the conclusion of Proposition 5.1 in [10, p. 71] allows marked points in the guise of what Hummel calls degenerate boundary components. We will apply Proposition 5.1 of [10] in the proof of Theorem 14.5 below after some preliminary constructions to fit its hypotheses.

Theorem 13.6. Let $\left(\pi: Q \rightarrow B, S_{*}, b_{0}\right)$ be a universal unfolding of a marked nodal Riemann surface $\left(\Sigma_{0}, s_{0, *}, \nu_{0}, j_{0}\right)$ of type $(g, n)$ and $\left(\Sigma_{k}, s_{k, *}, \nu_{k}, j_{k}\right)$ be a sequence of marked nodal Riemann surfaces of type $(g, n)$. Then the following are equivalent.
(i) The sequence $\left(\Sigma_{k}, s_{k, *}, \nu_{k}, j_{k}\right) D M$-converges to $\left(\Sigma_{0}, s_{0, *}, \nu_{0}, j_{0}\right)$.
(ii) After discarding finitely many terms there is a sequence $b_{k} \in B$ such that $b_{k}$ converges to $b_{0}$ and $\left(\Sigma_{k}, s_{k, *}, \nu_{k}, j_{k}\right)$ arises from a desingularization $u_{k}: \Sigma_{k} \rightarrow Q_{b_{k}}$.

We postpone the proof of Theorem 13.6 till after we treat the analogous theorem for fiber isomorphisms.

Definition 13.7. Let $\left(\pi_{A}: P \rightarrow A, R_{*}, a_{0}\right)$ and $\left(\pi_{B}: Q \rightarrow B, S_{*}, b_{0}\right)$ be two unfoldings of type $(g, n)$ and $f_{k}: P_{a_{k}} \rightarrow Q_{b_{k}}$ be a sequence of fiber isomorphisms. The sequence $f_{k}$ DM-converge to a fiber isomorphism $f_{0}: P_{a_{0}} \rightarrow Q_{b_{0}}$ iff $a_{k} \rightarrow a_{0}, b_{k} \rightarrow b_{0}$, and for every Hardy decomposition $P=M \cup N$ as in Definition 11.2 the sequence $f_{k} \circ \iota_{a_{k}}$ converges to $f_{0} \circ \iota_{a_{0}}$ in the $C^{\infty}$ topology.

Theorem 13.8. Let $\left(\pi_{A}: P \rightarrow A, R_{*}, a_{0}\right)$ and $\left(\pi_{B}: Q \rightarrow B, S_{*}, b_{0}\right)$ be two universal unfoldings of type $(g, n)$ and $a_{k} \rightarrow a_{0}$ and $b_{k} \rightarrow b_{0}$ be convergent sequences. Let $(\Phi, \phi)$ : $(P, A) \rightarrow(Q, B)$ be the germ of a morphism satisfying $\phi\left(a_{0}\right)=b_{0}$ and $\Phi_{a_{0}}=f_{0}$. Then the following are equivalent.
(i) The sequence $\left(a_{k}, f_{k}, b_{k}\right) D M$-converges to $\left(a_{0}, f_{0}, b_{0}\right)$.
(ii) For $k$ sufficiently large we have $\phi\left(a_{k}\right)=b_{k}$ and $\Phi_{a_{k}}=f_{k}$.

Proof. That (ii) implies (i) is obvious. We prove that (i) implies (ii). Recall the Hardy decomposition as in the definition of the spaces $\mathcal{U}, \mathcal{V}, \mathcal{W}$ in 11.4 The proof of Theorem 5.4 in Section 12 shows that

$$
\left(a, \Phi_{a} \mid \partial N \cap P_{a}, \phi(a)\right)=\mathcal{U}_{a} \cap \mathcal{V}_{a}
$$

But $\left(a_{k}, f_{k} \mid \partial N \cap P_{a_{k}}, b_{k}\right) \in \mathcal{U}_{a_{k}} \cap \mathcal{V}_{a_{k}} \subset \mathcal{W}$ for $k$ sufficiently large by DM-convergence. Both sequences $\left(a_{k}, \Phi_{a_{k}} \mid \partial N \cap P_{a_{k}}, \phi\left(a_{k}\right)\right)$ and $\left(a_{k}, f_{k} \mid \partial N \cap P_{a_{k}}, b_{k}\right)$ converge to the same point ( $a_{0}, f_{0} \mid \partial N \cap P_{a_{0}}, b_{0}$ ). Hence by transversality in Theorem 11.9 they are equal for large $k$. Now use Lemma 11.8

Proof of Theorem 13.6. We prove that (ii) implies (i). Let $u_{0}: \Sigma_{0} \rightarrow Q_{b_{0}}$ be a desingularization. Assume that $b_{k}$ converges to $b$ and that $u_{k}: \Sigma_{k} \rightarrow Q_{b_{k}}$ is a sequence of desingularizations. Choose a Hardy trivialization ( $Q=M \cup N, \iota, \rho$ ) for $\left(\pi, S_{*}, b_{0}\right)$ as in Definition 11.6 For each $b \in B$ choose a smooth map

$$
\psi_{b}: Q_{b} \rightarrow Q_{b_{0}}
$$

as follows. The restriction of $\psi_{b}$ to $M_{b}$ agrees with $\rho_{b}$. Next, using the nodal coordinates of Definition 11.2, extend $\psi_{b}$ to a neighborhood of the common boundary of $M$ and $N$ via $\left(x_{i}, 0, t_{i}\right) \mapsto\left(x_{i}, 0,0\right)$ for $2 \sqrt{\left|z_{i}(b)\right|} \leq\left|x_{i}\right| \leq 1$ and $\left(0, y_{i}, t_{i}\right) \mapsto\left(0, y_{i}, 0\right)$ for $2 \sqrt{\left|z_{i}(b)\right|} \leq\left|y_{i}\right| \leq 1$. Finally, when $z_{i}(b) \neq 0$, extend to a smooth map $Q_{b} \cap N_{i} \rightarrow$ $Q_{b_{0}} \cap N_{i}$ that maps the circle $\left|x_{i}\right|=\left|y_{i}\right|=\sqrt{\left|z_{i}(b)\right|}$ onto the nodal point $q_{i}$ and is a diffeomorphism from the complement of this circle in $Q_{b} \cap N_{i}$ onto the complement of $q_{i}$ in $Q_{b_{0}} \cap N_{i}$. Define

$$
\gamma_{k}:=\bigcup_{z_{i}\left(b_{k}\right) \neq 0} u_{k}^{-1}\left(\left\{q \in Q_{b} \cap N_{i}:\left|x_{i}(q)\right|=\left|y_{i}(q)\right|=\sqrt{\left.\left|z_{i}\left(b_{k}\right)\right|\right\}}\right) \subset \Sigma_{k} .\right.
$$

Then, for every $k$, there is a unique smooth map $\phi_{k}: \Sigma_{k} \backslash \gamma_{k} \rightarrow \Sigma_{0}$ such that

$$
u_{0} \circ \phi_{k}=\psi_{b_{k}} \circ u_{k}: \Sigma_{k} \backslash \gamma_{k} \rightarrow Q_{b_{0}}
$$

It follows that $\phi_{k}$ is a sequence of deformations as in Definition 13.2 and that this sequence satisfies the requirements of Definition 13.3 (The sequence $\phi_{k}$ is monotypic whenever there is an index set $I$ such that, for every $k$, we have $z_{i}\left(b_{k}\right)=0$ for $i \in I$ and $z_{k}\left(b_{i}\right) \neq 0$ for $i \notin I$; after discarding finitely many terms, we can write $\phi_{k}$ as a finite union of monotypic sequences.) Hence the sequence ( $\Sigma_{k}, s_{k, *}, \nu_{k}, j_{k}$ ) DM-converges to ( $\Sigma, j, s_{*}, \nu$ ). Thus we have proved that (ii) implies (i).

We prove that (i) implies (ii). Let ( $\Sigma_{k}, s_{k, *}, \nu_{k}, j_{k}$ ) be a sequence of marked nodal Riemann surfaces of type ( $g, n$ ) that DM-converges to ( $\Sigma, j, s_{*}, \nu$ ). If $\Sigma$ has no nodes then $\Sigma_{k}$ has no nodes and the maps $\phi_{k}: \Sigma_{k} \rightarrow \Sigma$ in the definition of DM-convergence are diffeomorphisms. Since $\left(\phi_{k}\right)_{*} j_{k}$ converges to $j$, assertion (ii) follows from the fact that a slice in $\mathcal{J}(\Sigma)$ determines a universal unfolding. The same reasoning works when $\left(\Sigma_{k}, s_{k, *}, v_{k}\right)$ has the same signature as ( $\Sigma, s_{*}, v$ ). To avoid excessive notation we consider the case where $(\Sigma, \nu)$ has precisely one node and ( $\Sigma_{k}, \nu_{k}$ ) has no nodes, i.e.

$$
v_{k}=\emptyset, \quad v=:\left\{\left\{z_{0}, z_{\infty}\right\}\right\} .
$$

Choose holomorphic diffeomorphisms

$$
x:\left(\Delta_{0}, z_{0}\right) \rightarrow(\mathbb{D}, 0), \quad y:\left(\Delta_{\infty}, z_{\infty}\right) \rightarrow(\mathbb{D}, 0),
$$

where $\Delta_{0}, \Delta_{\infty} \subset \Sigma$ are disjoint closed disks centered at $z_{0}, z_{\infty}$ respectively and

$$
\Delta:=\Delta_{0} \cup \Delta_{\infty}
$$

does not contain any marked points. For $\delta \in(0,1)$ let $\Delta(\delta):=\Delta_{0}(\delta) \cup \Delta_{\infty}(\delta)$ where

$$
\Delta_{0}(\delta):=\left\{p \in \Delta_{0}:|x(p)| \leq \delta\right\}, \quad \Delta_{\infty}(\delta):=\left\{q \in \Delta_{\infty}:|y(q)| \leq \delta\right\}
$$

A decreasing sequence $\delta_{k} \in(0,1)$ converging to zero determines a sequence of decompositions

$$
\Sigma=\Omega_{k} \cup \Delta\left(\delta_{k}\right), \quad \partial \Omega_{k}=\partial \Delta\left(\delta_{k}\right)=\Omega_{k} \cap \Delta\left(\delta_{k}\right)
$$

Thus $\Omega_{k}$ is obtained from $\Sigma$ by removing a nested sequence of pairs of open disks centered at the nodal points so $\bigcup_{k} \Omega_{k}=\Sigma \backslash\left\{z_{0}, z_{\infty}\right\}, \Omega_{k} \subset \Omega_{k+1}$, and $\Omega_{k} \cap \Delta=$ $\left(\Omega_{k} \cap \Delta_{0}\right) \cup\left(\Omega_{k} \cap \Delta_{\infty}\right)$ is a disjoint union of two closed annuli.

Claim. There are sequences of real numbers $\delta_{k}, r_{k}, \theta_{0 k}, \theta_{\infty k}$, smooth embeddings

$$
f_{k}: \Omega_{k} \rightarrow \Sigma_{k}, \quad \xi_{k}: \mathbb{A}\left(\delta_{k}, 1\right) \rightarrow \mathbb{A}\left(r_{k}, 1\right), \quad \eta_{k}: \mathbb{A}\left(\delta_{k}, 1\right) \rightarrow \mathbb{A}\left(r_{k}, 1\right),
$$

and holomorphic diffeomorphisms

$$
h_{k}: \mathbb{A}\left(r_{k}, 1\right) \rightarrow A_{k}:=\Sigma_{k} \backslash f_{k}(\Sigma \backslash \Delta),
$$

satisfying the following conditions.

1) $f_{k}^{*} j_{k}$ converges to $j$ in the $C^{\infty}$ topology on $\Sigma \backslash\left\{z_{0}, z_{\infty}\right\}$.
2) $f_{k}^{*} j_{k}$ is equal to $j$ on $\Omega_{k} \cap \Delta(1 / 2)$.
3) $\xi_{k}\left(S^{1}\right)=\eta_{k}\left(S^{1}\right)=S^{1}$.
4) $h_{k}\left(\xi_{k}(x(p))\right)=f_{k}(p)$ for $p \in \Omega_{k} \cap \Delta_{0}$.
5) $h_{k}\left(r_{k} / \eta_{k}(y(q))\right)=f_{k}(q)$ for $q \in \Omega_{k} \cap \Delta_{\infty}$.
6) $\xi_{k}(x(p))=e^{i \theta_{0 k}} x(p)$ for $p \in \Omega_{k} \cap \Delta_{0}(1 / 2)$.
7) $\eta_{k}(y(q))=e^{i \theta_{\infty k}} y(q)$ for $q \in \Omega_{k} \cap \Delta_{\infty}(1 / 2)$.

Proof of the Claim. Let $\delta_{k} \in(0,1]$ be any sequence decreasing to zero, for example $\delta_{k}:=$ $1 / k$, and set $\Omega_{k}:=\Sigma \backslash \operatorname{int}\left(\Delta\left(\delta_{k}\right)\right)$. Define $f_{k}: \Omega_{k} \rightarrow \Sigma_{k}$ by $f_{k}:=\left(\phi_{k} \mid \phi_{k}^{-1}\left(\Omega_{k}\right)\right)^{-1}$ where $\phi_{k}: \Sigma_{k} \backslash \gamma_{k} \rightarrow \Sigma$ is as in Definition 13.3. Then $f_{k}$ satisfies 1 ). We will modify $\delta_{k}$ and $f_{k}$ to satisfy the other conditions.

By the path lifting arguments used in the proof of Theorem7.1 (see also Appendix C. 5 of [16]) there is a sequence of holomorphic embeddings

$$
g_{k}:\left(\Omega_{k} \cap \Delta, j\right) \rightarrow\left(\Omega_{k}, f_{k}^{*} j_{k}\right)
$$

that converges to the identity in the $C^{\infty}$ topology and preserves the boundary of $\Omega_{k}$. Extend $g_{k}$ to a diffeomorphism, still denoted by $g_{k}: \Omega_{k} \rightarrow \Omega_{k}$, so that the extensions converge to the identity in the $C^{\infty}$ topology and replace $f_{k}$ by $f_{k} \circ g_{k}$. This new sequence satisfies 1 ) and 2); in fact, $f_{k}$ is now holomorphic on $\Omega_{k} \cap \Delta$. (Below we modify $f_{k}$ again.)

The set $A_{k} \subset \Sigma_{k}$ is an annulus with boundary $f_{k}\left(\partial \Delta_{0}\right) \cup f_{k}\left(\partial \Delta_{\infty}\right)$ so there is a unique number $r_{k}>0$ and a holomorphic diffeomorphism $h_{k}: \mathbb{A}\left(r_{k}, 1\right) \rightarrow A_{k}$, unique up to composition with a rotation, such that

$$
h_{k}\left(S^{1}\right)=f_{k}\left(\partial \Delta_{0}\right), \quad h_{k}\left(r_{k} S^{1}\right)=f_{k}\left(\partial \Delta_{\infty}\right)
$$

The embeddings $\xi_{k}: \mathbb{A}\left(\delta_{k}, 1\right) \rightarrow \mathbb{A}\left(r_{k}, 1\right)$ and $\eta_{k}: \mathbb{A}\left(\delta_{k}, 1\right) \rightarrow \mathbb{A}\left(r_{k}, 1\right)$ defined by 4$)$ and 5) satisfy 3 ); they are holomorphic because $f_{k}$ is holomorphic on $\Omega_{k} \cap \Delta$. Hence by Lemma 13.10 below, $r_{k}<\delta_{k}$ and so $r_{k}$ converges to zero.

By Lemma 13.11 below, there are sequences $\varepsilon_{k}>0, \rho_{k}>\delta_{k}$, and $\theta_{0 k}, \theta_{\infty k} \in[0,2 \pi]$ such that $\varepsilon_{k}$ and $\rho_{k}$ converge to zero and

$$
\left|x^{-1} \xi_{k}(x)-e^{i \theta_{0 k}}\right| \leq \varepsilon_{k}, \quad\left|y^{-1} \eta_{k}(y)-e^{i \theta_{\infty k}}\right| \leq \varepsilon_{k}
$$

for $x, y \in \mathbb{A}\left(\rho_{k}, 1\right)$. To see this let $\delta(m)>0$ be the constant of Lemma 13.11 with $\varepsilon=$ $\rho=1 / m$, choose an increasing sequence of integers $k_{m}$ such that $\delta_{k} \leq \delta(m)$ for $k \geq k_{m}$, and define $\varepsilon_{k}:=\rho_{k}:=1 / m$ for $k_{m} \leq k<k_{m+1}$. We call this kind of argument proof by patience. It follows that the maps $x \mapsto e^{-i \theta_{0 k}} \xi_{k}(x)$ and $y \mapsto e^{-i \theta_{\infty k}} \eta_{k}(y)$ converge to the identity uniformly with all derivatives on every compact subset of $\operatorname{int}(\mathbb{D}) \backslash 0$.

Next we construct two sequences of diffeomorphisms $\alpha_{k}, \beta_{k}: \mathbb{D} \rightarrow \mathbb{D}$, converging to the identity in the $C^{\infty}$ topology, and an exhausting sequence of closed annuli $B_{k} \subset$ $\operatorname{int}(\mathbb{D}) \backslash 0$, such that $\alpha_{k}$ and $\beta_{k}$ are equal to the identity in a neighborhood of $S^{1}=\partial \mathbb{D}$ and

$$
\xi_{k}\left(\alpha_{k}(x)\right)=e^{i \theta_{0 k}} x, \quad \eta_{k}\left(\beta_{k}(y)\right)=e^{i \theta_{\infty k}} y
$$

for $x, y \in B_{k}$. The assertion is obvious by an interpolation argument when the sequence $B_{k}$ is replaced by a single closed annulus $B \subset \operatorname{int}(\mathbb{D}) \backslash 0$. Now argue by patience as above.

Increasing $\delta_{k}$ if necessary we may assume that $A\left(\delta_{k}, 1 / 2\right) \subset B_{k}$ for all $k$. Define $\Omega_{k}:=\Sigma \backslash \operatorname{int}\left(\Delta\left(\delta_{k}\right)\right)$ as above. Now replace $\xi_{k}$ by $\xi_{k} \circ \alpha_{k}$ and $\eta_{k}$ by $\eta_{k} \circ \beta_{k}$. These functions satisfy 6) and 7). Redefine $f_{k}$ so that 4) and 5) hold with the new definitions of $\xi_{k}$ and $\eta_{k}$. Thus we have proved the claim.

In the following we assume without loss of generality that $\left(\pi: Q \rightarrow B, S_{*}, b_{0}\right)$ is the universal unfolding of $\left(\Sigma, s_{*}, \nu, j\right)$ constructed in the proof of Theorem 5.6 Now define the marked Riemann surface $\left(\Sigma_{k}^{\prime}, s_{k, *}^{\prime}, j_{k}^{\prime}\right)$ by

$$
\Sigma_{k}^{\prime}:=\left(\Sigma \backslash \operatorname{int}\left(\Delta\left(\sqrt{r_{k}}\right)\right)\right) / \sim
$$

where

$$
j_{k}^{\prime}:=f_{k}^{*} j_{k}, \quad s_{k, i}^{\prime}:=f_{k}^{-1}\left(s_{k, i}\right)
$$

and where the equivalence relation is defined by

$$
p \sim q \Leftrightarrow x(p) y(q)=z_{k}, z_{k}:=r_{k} e^{-i\left(\theta_{0 k}+\theta_{\infty k}\right)}
$$

for $p \in \Delta_{0}$ and $q \in \Delta_{\infty}$ with $|x(p)|=|y(q)|=\sqrt{r_{k}}$. Then, after removing finitely many terms, there is a sequence of regular values $b_{k} \in B$ of $\pi: Q \rightarrow B$ and a sequence of desingularizations $u_{k}^{\prime}: \Sigma_{k}^{\prime} \rightarrow Q_{b_{k}}$ such that

$$
u_{k}^{\prime}\left(s_{k, i}^{\prime}\right)=S_{i} \cap Q_{b_{k}}
$$

and $j_{k}^{\prime}$ is the pullback of the complex structure on $Q_{b_{k}}$ under $u_{k}^{\prime}$. This follows from Theorem 8.9 and the construction of a universal unfolding in the proof of Theorem5.6 Moreover, $\left(\Sigma_{k}^{\prime}, s_{k, *}^{\prime}, j_{k}^{\prime}\right)$ is isomorphic to ( $\Sigma_{k}, s_{k, *}, j_{k}$ ). An explicit isomorphism is the map $\psi_{k}: \Sigma_{k}^{\prime} \rightarrow \Sigma_{k}$ defined by

$$
\psi_{k}(p):= \begin{cases}f_{k}(p) & \text { for } p \in \Sigma_{k}^{\prime} \backslash \Delta \\ h_{k}\left(\xi_{k}(x(p))\right) & \text { for } p \in \Delta_{0} \text { with } \delta_{k} \leq|x(p)| \leq 1, \\ h_{k}\left(e^{i \theta_{0 k}} x(p)\right) & \text { for } p \in \Delta_{0} \text { with } \sqrt{r_{k}} \leq|x(p)| \leq \delta_{k}, \\ h_{k}\left(r_{k} / \eta_{k}(y(p))\right) & \text { for } p \in \Delta_{\infty} \text { with } \delta_{k} \leq|y(p)| \leq 1, \\ h_{k}\left(r_{k} / e^{i \theta_{\infty k}} y(p)\right) & \text { for } p \in \Delta_{\infty} \text { with } \sqrt{r_{k}} \leq|y(p)| \leq \delta_{k}\end{cases}
$$

That (i) implies (ii) in the case of a single node follows immediately with

$$
u_{k}:=u_{k}^{\prime} \circ \psi_{k}^{-1}: \Sigma_{k} \rightarrow Q_{b_{k}} .
$$

The case of several nodes is analogous. This proves Theorem 13.6
Remark 13.9. The sequence $u_{k}$ just constructed is such that $u_{k}\left(\gamma_{k}\right)$ converges to the nodal set in $Q_{b_{0}}$ and $u_{k} \circ \phi_{k}^{-1}: \Sigma \backslash \bigcup v \rightarrow Q$ converges to $u_{0} \mid(\Sigma \backslash \bigcup v)$ in the $C^{\infty}$ topology. To prove this, note that

$$
\psi_{k}^{-1}\left(\gamma_{k}\right) \subset\left\{[p]=[q] \in \Sigma_{k}^{\prime}: \sqrt{r_{k}} \leq|x(p)|,|y(q)| \leq \delta_{k}\right\} .
$$

Hence, by Step 1, $u_{k}\left(\gamma_{k}\right)$ converges to the nodal point in $Q_{b_{0}}$. Moreover, the main part of $\Sigma_{k}^{\prime}$ can be identified with the subset $\Omega_{k} \subset \Sigma$ (exhausting $\Sigma \backslash \bigcup v$ in the limit $k \rightarrow \infty$ ), the sequence $u_{k}^{\prime}$ converges to $u_{0}$ on $\Sigma \backslash \bigcup \nu$ under this identification, and $\phi_{k} \circ \psi_{k}: \Omega_{k} \rightarrow$ $\Sigma$ converges to the identity under this identification.

Lemma 13.10. If there is a holomorphic map $f: \mathbb{A}\left(r_{1}, R_{1}\right) \rightarrow \mathbb{A}\left(r_{2}, R_{2}\right)$ inducing an isomorphism of fundamental groups, then $R_{1} / r_{1} \leq R_{2} / r_{2}$.

Proof. The result is due to Huber [9]; an exposition appears in [14, Theorem 6.1, p. 14]. The proof uses the Schwarz-Pick-Ahlfors lemma (a holomorphic map from the unit disk to itself is a contraction in the Poincare metric). The circle of radius $\sqrt{r_{1} R_{1}}$ is a geodesic of length $2 \pi^{2} / \log \left(R_{1} / r_{1}\right)$ in the hyperbolic metric; its image under $f$ is shorter and hence so is the central geodesic in $\mathbb{A}\left(r_{2}, R_{2}\right)$.
Lemma 13.11. For every $\varepsilon>0$ and every $\rho>0$ there is a constant $\delta \in(0, \rho)$ such that the following holds. If $u: \mathbb{A}(\delta, 1) \rightarrow \mathbb{D} \backslash 0$ is a holomorphic embedding such that $u\left(S^{1}\right)=S^{1}$ then there is a real number $\theta$ such that

$$
x \in \mathbb{A}(\rho, 1) \Rightarrow\left|x^{-1} u(x)-e^{i \theta}\right|<\varepsilon
$$

Proof. It suffices to assume $u(1)=1$ and then prove the claim with $\theta=0$. Suppose by contradiction that there exist constants $\varepsilon>0$ and $\rho>0$ such that the assertion is wrong. Then there exists a sequence $\delta_{i}>0$ converging to zero and a sequence of holomorphic embeddings $u_{i}: \mathbb{A}\left(\delta_{i}, 1\right) \rightarrow \mathbb{D} \backslash 0$ such that

$$
u_{i}\left(S^{1}\right)=S^{1}, \quad u_{i}(1)=1, \quad \sup _{\rho \leq|x| \leq 1}\left|u_{i}(x)-x\right| \geq \varepsilon \rho
$$

We claim that $u_{i}$ converges to the identity, uniformly on every compact subset of $\mathbb{D} \backslash 0$. To see this extend $u_{i}$ to the annulus $\mathbb{A}\left(\delta_{i}, 1 / \delta_{i}\right)$ by the formula

$$
u_{i}(z):=1 / \overline{u_{i}(1 / \bar{z})}
$$

for $1 \leq|z| \leq 1 / \delta_{i}$. Think of the extended map as a holomorphic embedding $u_{i}$ : $\mathbb{A}\left(\delta_{i}, 1 / \delta_{i}\right) \rightarrow S^{2} \backslash\{0, \infty\}$. Next we claim that

$$
\begin{equation*}
\sup _{i} \sup _{z \in K}\left|d u_{i}(z)\right|<\infty \tag{53}
\end{equation*}
$$

for every compact subset $K \subset \mathbb{C} \backslash 0$. Namely, the energy of the holomorphic curve $u_{i}$ is bounded by the area of the target manifold $S^{2}$. So if $\left|d u_{i}\left(z_{i}\right)\right| \rightarrow \infty$ for some sequence $z_{i} \rightarrow z_{0} \in \mathbb{C} \backslash 0$, then a holomorphic sphere bubbles off near $z_{0}$ and it follows that a subsequence of $u_{i}$ converges to a constant, uniformly on every compact subset of $\mathbb{C} \backslash\left\{0, z_{0}\right\}$. But this contradicts the fact that $u_{i}\left(S^{1}\right)=S^{1}$. Thus we have proved 53). Now it follows from the standard elliptic bootstrapping techniques (or alternatively from Cauchy's integral formula and the Arzelà-Ascoli theorem) that there is a subsequence, still denoted by $u_{i}$, that converges in the $C^{\infty}$ topology to a holomorphic curve $u_{0}: \mathbb{C} \backslash 0$ $\rightarrow S^{2} \backslash\{0, \infty\}$. By the removable singularity theorem, $u_{0}$ extends to a holomorphic curve $u_{0}: S^{2} \rightarrow S^{2}$. Since $u_{i}$ is an embedding for every $i$, it follows that $u_{0}$ is an embedding and hence a Möbius transformation. Since $u_{i}\left(S^{1}\right)=S^{1}, u_{i}(1)=1$ and $0 \notin u_{i}\left(\mathbb{A}\left(\delta_{i}, 1\right)\right)$, it follows that

$$
u_{0}\left(S^{1}\right)=S^{1}, \quad u_{0}(1)=1, \quad u_{0}(0)=0
$$

This implies $u_{0}=\mathrm{id}$. Thus we have proved that $u_{i}$ converges to the identity, uniformly on every compact subset of $\mathbb{D} \backslash 0$. This contradicts the inequality $\sup _{\rho \leq|x| \leq 1}\left|u_{i}(x)-x\right| \geq \varepsilon \rho$ and this contradiction proves the lemma.

## 14. Compactness

In this section we prove that every sequence of stable marked nodal Riemann surfaces of type $(g, n)$ has a DM-convergent subsequence. Our strategy is to perform some preliminary constructions to reduce our compactness theorem to Proposition 5.1 of [10, p. 71]. We begin by rephrasing Hummel's result in a weaker form that we will apply directly (see Proposition 14.4 below).
14.1. Let $W$ be a smooth oriented surface, possibly with boundary and not necessarily compact or connected. A finite extension of $W$ is a smooth orientation preserving embedding $\iota: W \rightarrow S$ into a compact oriented surface $S$ such that $S \backslash \iota(W)$ is finite. If $\iota_{1}: W \rightarrow S_{1}$ and $\iota_{2}: W \rightarrow S_{2}$ are two such extensions, the map $\iota_{2} \circ \iota_{1}^{-1}$ extends to a homeomorphism, but not necessarily to a diffeomorphism. Let $W_{1}, \ldots, W_{\ell}$ be the components of $W, S_{1}, \ldots, S_{\ell}$ be the corresponding components of a finite extension $S$, $g_{i}$ be the genus of $S_{i}, m_{i}$ be the number of boundary components of $W_{i}$, and $n_{i}$ be the number of points in $S_{i} \backslash \iota\left(W_{i}\right)$. The (unordered) list ( $g_{i}, m_{i}, n_{i}$ ) is called the signature of $W$. Two surfaces of finite type are diffeomorphic if and only if they have the same signature. (Compare 3.4 and 3.5) We say that $W$ is of stable type if $n_{i}>\chi\left(S_{i}\right)$ (at least one puncture point on an annulus or torus, at least two on a disk, and at least three on a sphere).
14.2. A hyperbolic metric on $W$ is a complete Riemannian metric $h$ of constant curvature -1 such that each boundary component is a closed geodesic. A finite extension of a complex structure $j$ on $W$ is a finite extension $\iota: W \rightarrow S$ such that $\iota_{*} j$ extends to a complex structure on $S$; we say $j$ has finite type if it admits a finite extension.

Proposition 14.3. Let $W$ be a surface of stable type. Then the operation which assigns to each hyperbolic metric on $W$ its corresponding complex structure (rotation by $90^{\circ}$ ) is bijective. It restricts to a bijection between hyperbolic metrics of finite area and complex structures of finite type.

Proof. The operation $h \mapsto j$ is injective by the removable singularity theorem and surjective by applying the uniformization theorem to the holomorphic double. If $j$ is of finite type, then the area is finite by [10, Proposition 3.9, p. 68]. If $h$ is of finite area, then $j$ is of finite type by [10, Proposition 3.6, p. 65].

Proposition 14.4 (Mumford-Hummel). Let $S$ be a compact connected surface with boundary and $x_{1}, \ldots, x_{n}$ be a sequence of marked points in the interior of $S$ such that $W:=S \backslash\left\{x_{1}, \ldots, x_{n}\right\}$ is of stable type. Write

$$
\partial S=: \partial_{1} S \cup \cdots \cup \partial_{m} S,
$$

where each $\partial_{i} S$ is a circle. Let $j_{k}$ be a sequence of complex structures on $S$ and $h_{k}$ be the corresponding sequence of hyperbolic metrics on $W$. Assume:
(a) The lengths of the closed geodesics in $W \backslash \partial W$ are bounded away from zero.
(b) The lengths of the boundary geodesics converge to zero.

Then there exists a subsequence, still denoted by $\left(j_{k}, h_{k}\right)$, a closed Riemann surface $(\Sigma, j)$ with distinct marked points $\xi_{1}, \ldots, \xi_{n}, \eta_{1}, \ldots, \eta_{m}$, a hyperbolic metric $h$ of finite area on $\Sigma \backslash\left\{\xi_{1}, \ldots, \xi_{n}, \eta_{1}, \ldots, \eta_{m}\right\}$, and a sequence of continuous maps $\phi_{k}: S \rightarrow \Sigma$ satisfying the following conditions.
(i) $\phi_{k}\left(x_{i}\right)=\xi_{i}$ for $i=1, \ldots, n$ and $\phi_{k}\left(\partial_{i} S\right)=\eta_{i}$ for $i=1, \ldots, m$.
(ii) The restriction of $\phi_{k}$ to $S \backslash \partial S$ is a diffeomorphism onto $\Sigma \backslash\left\{\eta_{1}, \ldots, \eta_{m}\right\}$.
(iii) $\left(\phi_{k}\right)_{*} j_{k}$ converges to $j$ on $\Sigma \backslash\left\{\eta_{1}, \ldots, \eta_{m}\right\}$.
(iv) $\left(\phi_{k}\right)_{*} h_{k}$ converges to $h$ on $\Sigma \backslash\left\{\xi_{1}, \ldots, \xi_{n}, \eta_{1}, \ldots, \eta_{m}\right\}$.

Proof. This follows from Proposition 5.1 in [10, p. 71]. The discussion preceding Proposition 5.1 in [10] explains how to extract the subsequence and how to construct the Riemann surface $(\Sigma, j)$ and the hyperbolic metric $h$.

Theorem 14.5. Every sequence of stable marked nodal Riemann surfaces of type ( $g, n$ ) has a DM-convergent subsequence.

Proof. Let ( $\Sigma_{k}, s_{k, *}, v_{k}, j_{k}$ ) be a sequence of marked nodal Riemann surfaces of type $(g, n)$. Passing to a subsequence if necessary, we may assume that all marked nodal surfaces in our sequence have the same signature (see Definition 3.4) and hence are diffeomorphic. Thus we assume that

$$
\left(\Sigma_{k}, s_{k, *}, \nu_{k}\right)=\left(\Sigma, s_{*}, \nu\right)
$$

is independent of $k$. Denote by $\Sigma^{*}$ the possibly disconnected and noncompact surface obtained from $\Sigma$ by removing the special points. Let $h_{k}$ be the hyperbolic metric on $\Sigma^{*}$ determined by $j_{k}$ (see Proposition 14.3).

Let $\ell_{k}^{1}$ be the length of the shortest geodesic in $\Sigma^{*}$ with respect to $h_{k}$. If a subsequence of the $\ell_{k}^{1}$ is bounded away from zero we can apply Proposition 14.4 to each component of $\Sigma$ and the assertion follows. Namely, the maps $\phi_{k}$ in Proposition 14.4 are deformations as in Definition 13.2

Hence assume $\ell_{k}^{1}$ converges to zero as $k$ tends to infinity and, for each $k$, choose a geodesic $\gamma_{k}^{1}$ with length $\ell_{k}^{1}$. Passing to a further subsequence and, if necessary, modifying $h_{k}$ by a diffeomorphism that fixes the marked and nodal points we may assume that the geodesics $\gamma_{k}^{1}$ are all homotopic and indeed equal. Thus

$$
\gamma_{k}^{1}=\gamma^{1}
$$

for every $k$. Now let $\ell_{k}^{2}$ be the length of the shortest geodesic in $\Sigma \backslash \gamma^{1}$ with respect to $h_{k}$. If a subsequence of $\ell_{k}^{2}$ is bounded away from zero we cut open $\Sigma$ along $\gamma^{1}$. Again the assertion follows by applying Proposition 14.4 to each component of the resulting surface with boundary.

Continue by induction. That the induction terminates follows from the fact that the geodesics in $\left(\Sigma^{*}, h_{k}\right)$ of lengths at most $2 \operatorname{arcsinh}(1)$ are pairwise disjoint and their number is bounded above by $3 g-3+N$, where $N$ is the number of special points (see 10 Lemma 4.1, p. 68]). This proves the theorem.

Lemma 14.6. Let $\left(\pi: P \rightarrow A, R_{*}, a_{0}\right)$ be a nodal unfolding and $C \subset P$ be the set of critical points of $\pi$. Then, after shrinking $A$ if necessary, there exists a closed subset $V \subset P$ and a smooth map $\rho: P \backslash V \rightarrow P_{a_{0}} \backslash V$ satisfying the following conditions.
(i) For every $a \in A$ we have $C \cap P_{a} \subset V \cap P_{a}=: V_{a}$; moreover $C \cap P_{a_{0}}=V_{a_{0}}$.
(ii) Each component of $V$ intersects $P_{a}$ either in a simple closed curve or in a nodal point.
(iii) For every $a \in A$ the restriction $\rho_{a}:=\rho \mid P_{a} \backslash V_{a}: P_{a} \backslash V_{a} \rightarrow P_{a_{0}} \backslash V_{a_{0}}$ is $a$ diffeomorphism; moreover $\rho_{a_{0}}=\mathrm{id}$.

Proof. Choose a Hardy trivialization $(P=M \cup N, \iota, \rho)$ as in 11.6 and write

$$
N=N_{1} \cup \cdots \cup N_{k}
$$

as in Definition 11.2 Let $\left(z_{i}, t_{i}\right): A \rightarrow U_{i} \subset \mathbb{D} \times \mathbb{C}^{m-1}$ and $\left(x_{i}, y_{i}, t_{i}\right): N_{i} \rightarrow \mathbb{D}^{2} \times$ $\mathbb{C}^{m-1}$ be the holomorphic coordinates of Definition 11.2 so that $z_{i}(\pi(p))=x_{i}(p) y_{i}(p)$ and the critical set $C \subset P$ has components

$$
C_{i}:=\left\{p \in N_{i}: x_{i}(p)=y_{i}(p)=0\right\} .
$$

Define

$$
V:=V_{1} \cup \cdots \cup V_{k}, \quad V_{i}:=\left\{p \in N_{i}:\left|x_{i}(p)\right|=\left|y_{i}(p)\right|=\sqrt{\left|z_{i}(\pi(p))\right|}\right\}
$$

This set satisfies (i) and (ii). The restriction of the trivialization $\rho: M \rightarrow M_{a_{0}}$ to $\partial N_{i} \subset$ $\partial N=\partial M$ is, in the above coordinates, given by $\rho\left(x_{i}, y_{i}, t_{i}\right)=\left(x_{i}, 0, t_{i}\right)$ for $\left|x_{i}\right|=1$ and by $\rho\left(x_{i}, y_{i}, t_{i}\right)=\left(0, y_{i}, t_{i}\right)$ for $\left|y_{i}\right|=1$. We extend this map by an explicit formula. Choose a smooth cutoff function $\beta:[1, \infty) \rightarrow[0,1]$ such that $\beta^{\prime}(r) \geq 0$ for every $r$ and

$$
\beta(r):= \begin{cases}r-1 & \text { for } 1 \leq r \leq 3 / 2 \\ 1 & \text { for } r \geq 2 .\end{cases}
$$

Then define the extension $\rho: N_{i} \backslash V_{i} \rightarrow P_{a_{0}}$ in local coordinates by

$$
\rho\left(x_{i}, y_{i}, t\right):= \begin{cases}\left(\beta\left(\sqrt{\left|x_{i}\right| /\left|y_{i}\right|}\right) x_{i}, 0, t_{i}\right) & \text { if }\left|x_{i}\right|>\left|y_{i}\right|, \\ \left(0, \beta\left(\sqrt{\left|y_{i}\right| /\left|x_{i}\right|}\right) y_{i}, t_{i}\right) & \text { if }\left|y_{i}\right|>\left|x_{i}\right| .\end{cases}
$$

The resulting map $\rho: P \backslash V \rightarrow P_{a_{0}}$ is smooth and satisfies (iii). This proves the lemma.

Proof of Theorem 6.6. Let $\left(\pi: Q \rightarrow B, S_{*}\right)$ be a universal family and denote by $(B, \Gamma)$ the associated etale groupoid of Definition 6.4 (see Theorem 6.5). We prove that this groupoid is proper. Thus let $\left(a_{k}, f_{k}, b_{k}\right)$ be a sequence in $\Gamma$ such that $a_{k}$ converges to $a_{0}$ and $b_{k}$ converges to $b_{0}$. We must show that there is a fiber isomorphism $f_{0}: Q_{a_{0}} \rightarrow Q_{b_{0}}$ such that a suitable subsequence of $f_{k} \mathrm{DM}$-converges to $f_{0}$ (see Definition 13.7). To see this choose desingularizations

$$
\iota: \Sigma \rightarrow Q_{a_{0}}, \quad \iota^{\prime}: \Sigma^{\prime} \rightarrow Q_{b_{0}} .
$$

Denote by $\left(\Sigma, s_{*}, v, j\right)$ and $\left(\Sigma^{\prime}, s_{*}^{\prime}, \nu^{\prime}, j^{\prime}\right)$ the induced marked nodal Riemann surfaces. Consider the following diagram:

Here the sets $V_{a}:=V \cap Q_{a}$ and the diffeomorphisms $\rho_{a}: Q_{a} \backslash V_{a} \rightarrow Q_{a_{0}} \backslash V_{a_{0}}$ are as in Lemma 14.6 for $a$ near $a_{0}$; similarly for $b$ near $b_{0}$. Moreover,

$$
\iota_{k}:=\rho_{a_{k}}^{-1} \circ \iota, \quad \iota_{k}^{\prime}:=\rho_{b_{k}}^{-1} \circ \iota^{\prime} .
$$

By definition, the pullback complex structures

$$
j_{k}:=\iota_{k}^{*} J\left|Q_{a_{k}}, \quad j_{k}^{\prime}:=\iota_{k}^{\prime *} J\right| Q_{b_{k}}
$$

converge to $j$, respectively $j^{\prime}$, in the $C^{\infty}$ topology on every compact subset of $\Sigma \backslash \nu$, respectively $\Sigma^{\prime} \backslash \nu^{\prime}$. By Lemma 14.6 , there exist exhausting sequences of open sets

$$
U_{k} \subset \Sigma \backslash v, \quad U_{k}^{\prime} \subset \Sigma^{\prime} \backslash v^{\prime}, \quad f_{k}\left(U_{k}\right) \subset U_{k}^{\prime}
$$

such that $j_{k}$ can be modified outside $U_{k}$ so as to converge in the $C^{\infty}$ topology on all of $\Sigma$ to $j$, and similarly for $j_{k}^{\prime}$. Then

$$
u_{k}:=\left(\iota_{k}^{\prime}\right)^{-1} \circ f_{k} \circ \iota_{k}: U_{k} \rightarrow \Sigma^{\prime}
$$

is a sequence of $\left(j_{k}, j_{k}^{\prime}\right)$-holomorphic embeddings such that $u_{k}\left(s_{*}\right)=s_{*}^{\prime}$. The argument in Remark 8.5 shows that, if the first derivatives of $u_{k}$ are uniformly bounded, then $u_{k}$ has a $C^{\infty}$ convergent subsequence. It also shows that a nonconstant holomorphic sphere in $Q$ bubbles off whenever the first derivatives of $u_{k}$ are not bounded. But bubbling cannot occur (in $\Sigma \backslash \nu$ ). To see this argue as follows. Suppose $z_{k}$ converges to $z_{0} \in \Sigma \backslash \nu$ and the derivatives of $u_{k}$ at $z_{k}$ blow up. Then the standard bubbling argument (see [16, Chapter 4]) applies. It shows that, after passing to a subsequence and modifying $z_{k}$ (without changing the limit), there are ( $i, j_{k}$ )-holomorphic embeddings $\varepsilon_{k}$ from the disk $\mathbb{D}_{k} \subset \mathbb{C}$, centered at zero with radius $k$, to $\Sigma$ such that $\varepsilon_{k}(0)=z_{k}$, the family of disks $\varepsilon_{k}\left(\mathbb{D}_{k}\right)$ converges to $z_{0}$, and $u_{k} \circ \varepsilon_{k}$ converges to a nonconstant $J$-holomorphic sphere $v_{0}: S^{2}=\mathbb{C} \cup \infty \rightarrow Q_{b_{0}}$. (The convergence is uniform with all derivatives on every compact subset of $\mathbb{C}$.) Hence the image of $v_{0}$ contains at least three special points. It follows that the image of $u_{k} \circ \varepsilon_{k}$ contains at least two special points for $k$ sufficiently large. But the image of $u_{k}$ contains no nodal points, the image of $\varepsilon_{k}$ contains at most one marked point, and $u_{k}$ maps the marked points of $\Sigma$ bijectively onto the marked points of $\Sigma^{\prime}$. Hence the image of $u_{k} \circ \varepsilon_{k}$ contains at most one special point, a contradiction.

This shows that bubbling cannot occur, as claimed, and hence a suitable subsequence of $u_{k}$ converges in the $C^{\infty}$ topology to a ( $j, j^{\prime}$ )-holomorphic curve $u_{0}: \Sigma \backslash v \rightarrow \Sigma^{\prime} \backslash \nu^{\prime}$. Now the removable singularity theorem shows that $u_{0}$ extends to a $\left(j, j^{\prime}\right)$-holomorphic
curve on all of $\Sigma$ and maps $v$ to $v^{\prime}$. That $u_{0}$ is bijective follows by applying the same argument to $f_{k}^{-1}$. Hence there exists a unique fiber isomorphism $f_{0}: Q_{a_{0}} \rightarrow Q_{b_{0}}$ such that $\iota^{\prime} \circ u_{0}=f_{0} \circ \iota$. By construction, the subsequence of $f_{k} \mathrm{DM}$-converges to $f_{0}$

Thus we have proved that the map $s \times t: \Gamma \rightarrow B \times B$ is proper. Hence, by Corollary 2.13, the quotient space $B / \Gamma$ is Hausdorff. Moreover, by Theorems 13.6 and 14.5 , it is sequentially compact. Since $B$ is second countable it follows that $B / \Gamma$ is compact. This completes the proof of Theorem 6.6

Corollary 14.7. Suppose that a sequence of marked nodal Riemann surfaces of type $(g, n)$ DM-converges to both $\left(\Sigma, s_{*}, v, j\right)$ and $\left(\Sigma^{\prime}, s_{*}^{\prime}, v^{\prime}, j^{\prime}\right)$. Then $\left(\Sigma, s_{*}, v, j\right)$ and ( $\Sigma^{\prime}, s_{*}^{\prime}, \nu^{\prime}, j^{\prime}$ ) are isomorphic.

Proof. Let $\left(\pi_{B}: Q \rightarrow B, S_{*}\right)$ be a universal family. By Theorem 13.6 there exist points $a_{0}, b_{0} \in B$ and sequences $a_{k} \rightarrow a_{0}, b_{k} \rightarrow b_{0}$ such that ( $\Sigma, s_{*}, \nu, j$ ) arises from a desingularization of $Q_{a_{0}},\left(\Sigma^{\prime}, s_{*}^{\prime}, v^{\prime}, j^{\prime}\right)$ arises from a desingularization of $Q_{b_{0}}$, and the fibers $Q_{a_{k}}$ and $Q_{b_{k}}$ are isomorphic. Hence, by Theorem 6.6 there exists a fiber isomorphism from $Q_{a_{0}}$ to $Q_{b_{0}}$, and so ( $\left.\Sigma, s_{*}, \nu, j\right)$ and $\left(\Sigma^{\prime}, s_{*}^{\prime}, \nu^{\prime}, j^{\prime}\right)$ are isomorphic.

## A. Fractional Sobolev spaces

In this appendix and the next we summarize, for the convenience of the reader, the basic properties of fractional Sobolev spaces used in this article.
A.1. For $s \geq 0$ denote by $H^{s}\left(S^{1}\right)$ the Hilbert space of all power series

$$
u\left(e^{i \theta}\right)=\sum_{n \in \mathbb{Z}} u_{n} e^{i n \theta}
$$

with coefficients $u_{n} \in \mathbb{C}$ whose norm

$$
\|u\|_{s}:=\|u\|_{H^{s}\left(S^{1}\right)}:=\sqrt{\sum_{n \in \mathbb{Z}}(1+|n|)^{2 s}\left|u_{n}\right|^{2}}
$$

is finite. Thus $H^{0}\left(S^{1}\right)=L^{2}\left(S^{1}\right)$ and, for $s>0$, we have $H^{s}\left(S^{1}\right) \subset L^{2}\left(S^{1}\right)$ with a compact dense inclusion.

Lemma A. 2 (Sobolev estimate). For every $s>1 / 2$ there is a constant $c>0$ such that every smooth function $u: S^{1} \rightarrow \mathbb{C}$ satisfies

$$
\|u\|_{L^{\infty}\left(S^{1}\right)} \leq c\|u\|_{H^{s}\left(S^{1}\right)} .
$$

Proof. The constant is $c=\sqrt{\sum_{n \in \mathbb{Z}}(1+|n|)^{-2 s}}$. For $z=e^{i x} \in S^{1}$ we have

$$
|u(z)| \leq \sum_{n \in \mathbb{Z}}\left|u_{n}\right|=\sum_{n \in \mathbb{Z}}(1+|n|)^{s}\left|u_{n}\right|(1+|n|)^{-s} \leq c\|u\|_{H^{s}\left(S^{1}\right)}
$$

where the last step is by the Cauchy-Schwarz inequality.

Lemma A. 3 (Weak product estimate). For all $t \geq s \geq 0$ with $t>1 / 2$ there is a constant $c>0$ such that, for all $u \in H^{s}\left(S^{1}\right)$ and $v \in H^{t}\left(S^{1}\right)$, we have

$$
\|u v\|_{H^{s}\left(S^{1}\right)} \leq c\|u\|_{H^{s}\left(S^{1}\right)}\|v\|_{H^{t}\left(S^{1}\right)} .
$$

Proof. The constant is

$$
c=\sup _{k \in \mathbb{Z}} \sqrt{\sum_{n \in \mathbb{Z}} \frac{(1+|k|)^{2 s}}{(1+|k-n|)^{2 s}(1+|n|)^{2 t}}}<\infty
$$

To see that this constant is finite assume $k>0$ and consider the sum over the four regions $n \leq 0,0 \leq n \leq k / 2, k / 2 \leq n \leq k$, and $n \geq k$. Now

$$
\begin{aligned}
\|u v\|_{s}^{2} \leq & \sum_{k \in \mathbb{Z}}(1+|k|)^{2 s}\left(\sum_{n \in \mathbb{Z}}\left|u_{k-n} \| v_{n}\right|\right)^{2} \\
\leq & \sum_{k \in \mathbb{Z}}\left(\sum_{n \in \mathbb{Z}} \frac{(1+|k|)^{2 s}}{}(1+|k-n|)^{2 s}(1+|n|)^{2 t}\right) \\
& \cdot\left(\sum_{n \in \mathbb{Z}}(1+|k-n|)^{2 s}\left|u_{k-n}\right|^{2}(1+|n|)^{2 t}\left|v_{n}\right|^{2}\right) \\
\leq & c^{2} \sum_{k \in \mathbb{Z}} \sum_{n \in \mathbb{Z}}(1+|k-n|)^{2 s}\left|u_{k-n}\right|^{2}(1+|n|)^{2 t}\left|v_{n}\right|^{2} \\
= & c^{2}\|u\|_{s}^{2}\|v\|_{t}^{2} .
\end{aligned}
$$

The third step follows from the Cauchy-Schwarz inequality. This proves the lemma.
A.4. The Fourier transform of a function $f: \mathbb{R} \rightarrow \mathbb{C}$ is defined by

$$
\mathcal{F}(f)(v):=\frac{1}{\sqrt{2 \pi}} \int_{-\infty}^{\infty} e^{-i v x} f(x) d x
$$

For $s \geq 0$ the $H^{s}(\mathbb{R})$ norm of $f$ is defined by

$$
\|f\|_{s}:=\|f\|_{H^{s}(\mathbb{R})}:=\sqrt{\int_{\mathbb{R}}(1+|v|)^{2 s}|\mathcal{F}(f)(v)|^{2} d v}
$$

The space $H^{s}(\mathbb{R})$ is defined to be the completion of the space of smooth functions of compact support in this norm. It is a Hilbert space.

Lemma A.5. For every closed interval $I \subset \mathbb{R}$ of length less than $2 \pi$ and every $s \geq 0$ there is a constant $c>0$ such that

$$
c^{-1}\|u\|_{H^{s}\left(S^{1}\right)} \leq\|f\|_{H^{s}(\mathbb{R})} \leq c\|u\|_{H^{s}\left(S^{1}\right)}
$$

whenever $f$ is supported in $I$ and $u\left(e^{i x}\right)=f(x)$ for $x \in I$ and $u\left(e^{i x}\right)=0$ for $x \notin$ $I+2 \pi \mathbb{Z}$.

Proof. Choose a smooth function $[0,1] \times S^{1} \rightarrow S^{1}:\left(t, e^{i x}\right) \mapsto \phi_{t}\left(e^{i x}\right)$ such that

$$
\phi_{t}\left(e^{i x}\right)=e^{-i t x} \quad \text { for } t \in[0,1] \text { and } x \in I .
$$

Then the Fourier coefficients of $\phi_{t} u$ are

$$
\left(\phi_{t} u\right)_{n}=\frac{1}{2 \pi} \int_{I} e^{-i n x} \phi_{t}\left(e^{i x}\right) u\left(e^{i x}\right) d x=\frac{1}{\sqrt{2 \pi}} \mathcal{F}(f)(n+t)
$$

and hence

$$
\left\|\phi_{t} u\right\|_{H^{s}\left(S^{1}\right)}^{2}=\frac{1}{2 \pi} \sum_{n \in \mathbb{Z}}(1+|n|)^{2 s}|\mathcal{F}(f)(n+t)|^{2}
$$

By Lemma A.3, there is a constant $c>0$ such that

$$
c^{-1}\|u\|_{H^{s}\left(S^{1}\right)} \leq\left\|\phi_{t} u\right\|_{H^{s}\left(S^{1}\right)} \leq c\|u\|_{H^{s}\left(S^{1}\right)}
$$

for every smooth function $u: S^{1} \rightarrow \mathbb{R}$ and every $t \in[0,1]$. Squaring this inequality and integrating over the interval $0 \leq t \leq 1$ gives

$$
c^{-2}\|u\|_{H^{s}\left(S^{1}\right)}^{2} \leq \frac{1}{2 \pi} \sum_{n \in \mathbb{Z}} \int_{0}^{1}(1+|n|)^{2 s}|\mathcal{F}(f)(n+t)|^{2} d t \leq c^{2}\|u\|_{H^{s}\left(S^{1}\right)}^{2}
$$

The assertion follows by comparing the factor $(1+|n|)^{2 s}$ with $(1+|n+t|)^{2 s}$; their ratio is bounded below by $2^{-2 s}$ and is bounded above by $2^{2 s}$ for all $n \in \mathbb{Z}$ and $t \in[0,1]$.
Lemma A.6. Assume $0<s<1$. Then there is a constant $c>0$ such that

$$
\begin{equation*}
\int_{\mathbb{R}}|\nu|^{2 s}|\mathcal{F}(f)(\nu)|^{2} d \nu=c \int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|f(x+t)-f(x)|^{2}}{|t|^{1+2 s}} d x d t \tag{54}
\end{equation*}
$$

for every compactly supported smooth function $f: \mathbb{R} \rightarrow \mathbb{C}$.
Proof. The constant is

$$
\frac{1}{c}:=4 \int_{0}^{\infty} \frac{1-\cos t}{t^{1+2 s}} d t
$$

To see this we observe that the Fourier transform of $f_{t}(x):=f(x+t)-f(x)$ is given by $\mathcal{F}\left(f_{t}\right)(v)=\left(e^{i v t}-1\right) \mathcal{F}(f)(v)$. Hence, by Plancherel's theorem, we have

$$
\begin{aligned}
\int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|f(x)-f(y)|^{2}}{|x-y|^{1+2 s}} d x d y & =\int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|f(x+t)-f(x)|^{2}}{|t|^{1+2 s}} d x d t \\
& =\int_{\mathbb{R}} \int_{\mathbb{R}} \frac{\left|e^{i v t}-1\right|^{2}}{|t|^{1+2 s}|\mathcal{F}(f)(v)|^{2} d v d t} \\
& =4 \int_{\mathbb{R}}\left(\int_{0}^{\infty} \frac{1-\cos |v| t}{|t|^{1+2 s}} d t\right)|\mathcal{F}(f)(\nu)|^{2} d v \\
& =4 \int_{\mathbb{R}}\left(\int_{0}^{\infty} \frac{1-\cos t}{|t|^{1+2 s}} d t\right)|v|^{2 s}|\mathcal{F}(f)(v)|^{2} d \nu
\end{aligned}
$$

This proves the lemma.

Corollary A.7. When $s$ is a nonnegative integer, the space $H^{s}(\mathbb{R})$ is the completion of the space of smooth functions of compact support in the norm $\sum_{j=0}^{s}\left\|d^{j} f\right\|_{L^{2}}$. If $s>0$ is not an integer $H^{s}(\mathbb{R})$ is the completion of the space of smooth functions of compact support in the norm $\sum_{j<s}\left(\left\|d^{j} f\right\|_{L^{2}}+\left\|d^{j} f\right\|_{s-k, 2}\right)$ where $k$ is the unique integer with $k<s<k+1$ and

$$
\|g\|_{\sigma, 2}:=\left(\int_{\mathbb{R}} \int_{\mathbb{R}} \frac{|g(x+t)-g(x)|^{2}}{|t|^{1+2 \sigma}} d x d t\right)^{1 / 2}
$$

Lemma A.8. Let $\alpha_{k}: \mathbb{R} \rightarrow[0,1]$ be a sequence of smooth cutoff functions, supported in $\left\{2^{k-1} \leq|\nu| \leq 2^{k+1}\right\}$ for $k \geq 1$ and in $[-2,2]$ for $k=0$, such that $\sum_{k} \alpha_{k} \equiv 1$. Denote by $a_{k}:=\overline{\mathcal{F}}^{-1}\left(\alpha_{k}\right)$ the inverse Fourier transform of $\alpha_{k}$. Then

$$
\sum_{k=0}^{\infty} 2^{2 s k}\left\|a_{k} * f\right\|_{L^{2}}^{2} \leq 4^{s}\|f\|_{s}^{2}
$$

Proof. Abbreviate $f_{k}:=a_{k} * f$ and $\phi_{k}:=\mathcal{F}\left(f_{k}\right)=\alpha_{k} \mathcal{F}(f)$. Then

$$
\left\langle f_{j}, f_{k}\right\rangle_{s}=\int_{-\infty}^{\infty}(1+|v|)^{2 s} \alpha_{j}(v) \alpha_{k}(v)|\mathcal{F}(f)(v)|^{2} d v \geq 0
$$

for all $j$ and $k$ and hence

$$
\|f\|_{s}^{2} \geq \sum_{k=0}^{\infty}\left\|f_{k}\right\|_{s}^{2} \geq \sum_{k=0}^{\infty} 2^{2(k-1) s}\left\|f_{k}\right\|_{s}^{2}
$$

This proves the lemma.
Lemma A.9. For every $s>0$ there is a constant $c>0$ such that the following holds. If $f=\sum_{k \geq 0} f_{k}$ and $\mathcal{F}\left(f_{k}\right)$ is supported in the interval $\left[-2^{k+2}, 2^{k+2}\right]$ then

$$
\|f\|_{s}^{2} \leq c \sum_{k=0}^{\infty} 2^{2 s k}\left\|f_{k}\right\|_{L^{2}}^{2}
$$

Proof. The constant is $c:=5^{2 s} /\left(1-2^{-2 s}\right)$. Define $\phi:=\mathcal{F}(f)$ and $\phi_{k}:=\mathcal{F}\left(f_{k}\right)$ and assume without loss of generality that $\phi_{k}$ is supported in the interval $\left[0,2^{k+2}\right]$. Then

$$
\begin{aligned}
\|f\|_{s}^{2}= & \int_{0}^{\infty}(1+|v|)^{2 s}\left|\sum_{k=0}^{\infty} \phi_{k}(v)\right|^{2} d v \\
= & \int_{0}^{4}(1+|v|)^{2 s}\left|\sum_{k=0}^{\infty} \phi_{k}(v)\right|^{2} d v \\
& +\sum_{j=0}^{\infty} \int_{2^{j+2}}^{2^{j+3}}(1+|v|)^{2 s}\left|\sum_{k=j+1}^{\infty} \phi_{k}(v)\right|^{2} d v \\
\leq & 5^{2 s}\left(\int_{0}^{4}\left|\sum_{k=0}^{\infty} \phi_{k}(\nu)\right|^{2} d v+\sum_{j=0}^{\infty} 2^{2(j+1) s} \int_{2^{j+2}}^{2^{j+3}}\left|\sum_{k=j+1}^{\infty} \phi_{k}(v)\right|^{2} d v\right)
\end{aligned}
$$

Now it follows from the Cauchy-Schwarz inequality that

$$
\begin{aligned}
\int_{0}^{4}\left|\sum_{k=0}^{\infty} \phi_{k}(\nu)\right|^{2} d v & \leq \int_{0}^{4}\left(\sum_{k=0}^{\infty} 2^{-2 k s}\right)\left(\sum_{k=0}^{\infty} 2^{2 k s}\left|\phi_{k}(\nu)\right|^{2}\right) d v \\
& =\frac{1}{1-2^{-2 s}} \sum_{k=0}^{\infty} 2^{2 k s} \int_{0}^{4}\left|\phi_{k}(\nu)\right|^{2} d v
\end{aligned}
$$

and, similarly,

$$
2^{2(j+1) s} \int_{2^{j+2}}^{2^{j+3}}\left|\sum_{k=j+1}^{\infty} \phi_{k}(v)\right|^{2} d v \leq \frac{1}{1-2^{-2 s}} \sum_{k=j+1}^{\infty} 2^{2 k s} \int_{2^{j+2}}^{2^{j+3}}\left|\phi_{k}(v)\right|^{2} d v
$$

The result follows by combining these three estimates.
Theorem A. 10 (Strong product estimate). For every $s \geq 0$ there is a constant $c>0$ such that

$$
\|f g\|_{H^{s}(\mathbb{R})} \leq c\left(\|f\|_{H^{s}(\mathbb{R})}\|g\|_{L^{\infty}(\mathbb{R})}+\|f\|_{L^{\infty}(\mathbb{R})}\|g\|_{H^{s}(\mathbb{R})}\right)
$$

for any two compactly supported smooth functions $f, g: \mathbb{R} \rightarrow \mathbb{C}$.
Proof. For $s>1$ we follow the beautiful argument by Bourgain, Brezis, and Mironescu in [1. Lemma D.2] which is based on the Littlewood-Paley decomposition; it simplifies slightly in our special case. Choose a smooth cutoff function $\beta: \mathbb{R} \rightarrow[0,1]$ such that

$$
\beta(\nu)= \begin{cases}1 & \text { for }|\nu| \leq 1, \\ 0 & \text { for }|\nu| \geq 2,\end{cases}
$$

and denote by $b:=\mathcal{F}^{-1}(\beta)$ its inverse Fourier transform. For every integer $k \geq 0$ define

$$
b_{k}(t):=2^{k} b\left(2^{k} t\right), \quad \beta_{k}(\nu):=\beta\left(2^{-k} v\right)
$$

so that $\beta_{k}=\mathcal{F}\left(b_{k}\right)$. Then there is a constant $c_{0}>0$ such that

$$
\begin{equation*}
\left\|b_{k}\right\|_{L^{1}} \leq c_{0}, \quad\left\|b_{k}^{\prime}\right\|_{L^{1}} \leq 2^{k} c_{0} \tag{55}
\end{equation*}
$$

for every $k$. Next define

$$
\alpha_{k}:=\beta_{k}-\beta_{k-1}, \quad a_{k}:=\mathcal{F}^{-1}\left(\alpha_{k}\right)=b_{k}-b_{k-1}
$$

for $k \geq 1$ and $\alpha_{0}:=\beta, a_{0}=b$ so that

$$
\beta_{k}=\sum_{j=0}^{k} \alpha_{j}, \quad b_{k}=\sum_{j=0}^{k} a_{j} .
$$

Then, for every smooth function $f: \mathbb{R} \rightarrow \mathbb{C}$ with compact support and $s \geq 0$, the series

$$
f=\sum_{k=0}^{\infty} a_{k} * f
$$

is absolutely summable in $H^{s}(\mathbb{R})$. Namely, the Fourier transform $\phi:=\mathcal{F}(f)$ lies in the Schwartz space and so decays faster than any rational function; hence the series $\phi=$ $\sum_{k=0}^{\infty} \alpha_{k} \phi$ is absolutely summable in the weighted $L^{2}$ space of all functions $\psi: \mathbb{R} \rightarrow \mathbb{C}$ for which $v \mapsto(1+|\nu|)^{s} \psi(v)$ is square integrable.

Given two smooth functions $f, g: \mathbb{R} \rightarrow \mathbb{C}$ with compact support write

$$
\begin{align*}
f g^{\prime} & =\sum_{j, k=0}^{\infty}\left(a_{j} * f\right)\left(a_{k}^{\prime} * g\right) \\
& =\sum_{j \leq k}\left(a_{j} * f\right)\left(a_{k}^{\prime} * g\right)+\sum_{j>k}\left(a_{j} * f\right)\left(a_{k}^{\prime} * g\right) \\
& =\sum_{k=0}^{\infty}\left(b_{k} * f\right)\left(a_{k}^{\prime} * g\right)+\sum_{j=1}^{\infty}\left(a_{j} * f\right)\left(b_{j-1}^{\prime} * g\right) . \tag{56}
\end{align*}
$$

The Fourier transform of $\left(b_{k} * f\right)\left(a_{k}^{\prime} * g\right)$ is the convolution of the functions $\beta_{k} \mathcal{F}(f)$ and $\alpha_{k} \mathcal{F}\left(g^{\prime}\right)$, both supported in the interval $\left[-2^{k+1}, 2^{k+1}\right]$, and so it is supported in the interval $\left[-2^{k+2}, 2^{k+2}\right]$. Hence

$$
\begin{aligned}
\left\|\left(b_{k} * f\right)\left(a_{k}^{\prime} * g\right)\right\|_{L^{2}} & \leq\left\|b_{k} * f\right\|_{L^{\infty}}\left\|a_{k} * g^{\prime}\right\|_{L^{2}} \leq c_{0}\|f\|_{L^{\infty}}\left\|a_{k}^{\prime} * g\right\|_{L^{2}} \\
& \leq c_{0} 2^{k+1}\|f\|_{L^{\infty}}\left\|a_{k} * g\right\|_{L^{2}} .
\end{aligned}
$$

The last step follows from the fact that $\mathcal{F}\left(a_{k}^{\prime}\right)(v)=i v \alpha_{k}(\nu)$ and $\alpha_{k}$ is supported in the domain $\left\{2^{k-1} \leq|\nu| \leq 2^{k+1}\right\}$. Similarly,

$$
\left\|\left(a_{k} * f\right)\left(b_{k-1}^{\prime} * g\right)\right\|_{L^{2}} \leq\left\|a_{k} * f\right\|_{L^{2}}\left\|b_{k-1}^{\prime} * g\right\|_{L^{\infty}} \leq c_{0} 2^{k}\left\|a_{k} * f\right\|_{L^{2}}\|g\|_{L^{\infty}}
$$

Now let $c_{1}$ be the constant of Lemma A. 9 with $s$ replaced by $s-1$. Then

$$
\begin{aligned}
\left\|f g^{\prime}\right\|_{s-1}^{2} & \leq c_{1} \sum_{k=0}^{\infty} 2^{2(s-1) k}\left\|\left(a_{k} * f\right)\left(b_{k-1}^{\prime} * g\right)+\left(a_{k} * f\right)\left(b_{k-1}^{\prime} * g\right)\right\|_{L^{2}}^{2} \\
& \leq 2 c_{1} \sum_{k=0}^{\infty} 2^{2(s-1) k}\left(\left\|\left(a_{k} * f\right)\left(b_{k-1}^{\prime} * g\right)\right\|_{L^{2}}^{2}+\left\|\left(a_{k} * f\right)\left(b_{k-1}^{\prime} * g\right)\right\|_{L^{2}}^{2}\right) \\
& \leq 2 c_{0} c_{1} \sum_{k=0}^{\infty} 2^{2 s k}\left(4\|f\|_{L^{\infty}}^{2}\left\|a_{k} * g\right\|_{L^{2}}^{2}+\left\|a_{k} * f\right\|_{L^{2}}^{2}\|g\|_{L^{\infty}}^{2}\right) \\
& =2 c_{0} c_{1} c_{2}\left(4\|f\|_{L^{\infty}}^{2}\|g\|_{s}^{2}+\|g\|_{L^{\infty}\|f\|_{s}^{2}}^{2}\right)
\end{aligned}
$$

The last inequality follows from Lemma A.8 with $c_{2}:=4^{s}$. Interchanging $f$ and $g$ and using the Leibniz rule we obtain

$$
\left\|(f g)^{\prime}\right\|_{s-1} \leq c^{\prime}\left(\|f\|_{L^{\infty}}\|g\|_{s}+\|g\|_{L^{\infty}}\|f\|_{s}\right)
$$

with $c^{\prime}:=\sqrt{10 c_{0} c_{1} c_{2}}$. Since

$$
\|f g\|_{L^{2}} \leq\|f\|_{L^{\infty}}\|g\|_{L^{2}} \leq\|f\|_{L^{\infty}}\|g\|_{s},
$$

this proves the theorem for $s>1$. For $0<s<1$ the result follows easily from Lemma A.6. For $s=0$ and $s=1$ the result is obvious. This proves the theorem.

Corollary A.11. For every $s \geq 0$ there is a constant $C>0$ such that

$$
\|u v\|_{H^{s}\left(S^{1}\right)} \leq C\left(\|u\|_{H^{s}\left(S^{1}\right)}\|v\|_{L^{\infty}\left(S^{1}\right)}+\|u\|_{L^{\infty}\left(S^{1}\right)}\|v\|_{H^{s}\left(S^{1}\right)}\right)
$$

for any two smooth functions $u, v: S^{1} \rightarrow \mathbb{C}$.
Proof. Lemma A. 5 and Theorem A. 10
Lemma A.12. Fix a constant $s>1 / 2$. Let $X \subset \mathbb{C}^{m}$ and $Y \subset \mathbb{C}^{n}$ be open sets and $f: X \rightarrow Y$ be a smooth map. Then

$$
H^{s}\left(S^{1}, X\right):=\left\{v \in H^{s}\left(S^{1}, \mathbb{C}^{m}\right): v\left(S^{1}\right) \subset X\right\}
$$

is an open subset of $H^{s}\left(S^{1}, \mathbb{C}^{m}\right)$ and $H^{s}\left(S^{1}, Y\right)$ is an open subset of $H^{s}\left(S^{1}, \mathbb{C}^{n}\right)$. Morever, composition with $f$ defines a smooth map

$$
\begin{equation*}
H^{s}\left(S^{1}, X\right) \rightarrow H^{s}\left(S^{1}, Y\right): u \mapsto f \circ u . \tag{57}
\end{equation*}
$$

Proof. This is Lemma C. 1 in [1]. We sketch the proof. That $H^{s}\left(S^{1}, X\right)$ and $H^{s}\left(S^{1}, Y\right)$ are open sets follows immediately from Lemma A. 2 . To prove that

$$
\begin{equation*}
u \in H^{s}\left(S^{1}, X\right) \Rightarrow f \circ u \in H^{s}\left(S^{1}, Y\right) \tag{58}
\end{equation*}
$$

we argue by induction. For $1 / 2<s \leq 1$ this follows from the estimates

$$
\|f \circ u\|_{s, 2} \leq c\|u\|_{s, 2}, \quad\left\|(f \circ u)^{\prime}\right\|_{L^{2}\left(S^{1}\right)} \leq c\left\|u^{\prime}\right\|_{L^{2}\left(S^{1}\right)}
$$

where $\|u\|_{s, 2}^{2}$ is as in Corollary A. 7 and $c$ is a Lipschitz constant for $f$ on the image of $u$ (which is compact by Lemma A.2); for $1<s \leq 3 / 2$ it follows from the identity

$$
(f \circ u)^{\prime}=d f(u) u^{\prime}
$$

with $d f(u) \in H^{1}, u^{\prime} \in H^{s-1}$ and so $(f \circ u)^{\prime} \in H^{s-1}$, by Lemma A.3. Fix an integer $k \geq 2$ and suppose, by induction, that (58) holds for $s \leq k-1 / 2$. Fix a real number $s$ with $k-1 / 2<s \leq k+1 / 2$. If $u \in H^{s}$, then by the induction hypothesis $d f(u) \in H^{s-1}$, and since $u^{\prime} \in H^{s-1}$ it follows from Lemma A. 3 with $s$ replaced by $s-1>1 / 2$ that $(f \circ u)^{\prime}=d f(u) u^{\prime} \in H^{s-1}$ and hence $f \circ u \in H^{s}$.

Thus we have proved (58). The same argument shows that the map (57) is bounded in the following sense: For every constant $c_{0}>0$ and every compact subset $K \subset X$ there is a constant $c>0$ such that

$$
u\left(S^{1}\right) \subset K,\|u\|_{H^{s}} \leq c_{0} \Rightarrow\|f \circ u\|_{H^{s}} \leq c
$$

for every $u \in H^{s}\left(S^{1}, X\right)$. It follows that the map

$$
\begin{equation*}
H^{s}\left(S^{1}, X\right) \rightarrow H^{s}\left(S^{1}, \operatorname{End}_{\mathbb{R}}\left(\mathbb{C}^{m}, \mathbb{C}^{n}\right)\right): u \mapsto d f(u) \tag{59}
\end{equation*}
$$

is bounded as well. This in turn implies that the map (57), and hence also (59), is continuous. That (57) is differentiable follows from the continuity of (59) and the estimate

$$
\begin{aligned}
\|f(u+\xi)-f(u)-d f(u) \xi\|_{H^{s}} & \leq \sup _{0 \leq t \leq 1}\|d f(u+t \xi) \xi-d f(u) \xi\|_{H^{s}} \\
& \leq c \sup _{\|\eta\|_{H^{s} \leq \delta} \leq \delta}\|d f(u+\eta)-d f(u)\|_{H^{s}}\|\xi\|_{H^{s}}
\end{aligned}
$$

for $u \in H^{s}\left(S^{1}, X\right)$ and $\xi \in H^{s}\left(S^{1}, \mathbb{C}^{m}\right)$ with $\|\xi\|_{H^{s}} \leq \delta$; here $c$ is the constant in Lemma A. 3 and we choose $\delta$ sufficiently small. Since the differential of 57] is a map of the same type it then follows by induction that (57) is smooth. This proves the lemma.

## B. An elliptic boundary estimate

B.1. Let $s \in \mathbb{R}$ and let $V$ be a finite-dimensional complex Hilbert space. Denote by $H^{s}\left(S^{1}, V\right)$ the Hilbert space of all power series

$$
v\left(e^{i \theta}\right)=\sum_{n \in \mathbb{Z}} v_{n} e^{i n \theta}
$$

with coefficients $v_{n} \in V$ whose norm

$$
\|v\|_{s}:=\|v\|_{H^{s}\left(S^{1}\right)}:=\sqrt{\sum_{n \in \mathbb{Z}}(1+|n|)^{2 s}\left|v_{n}\right|^{2}}
$$

is finite. The crucial properties of these spaces are the following.
(i) If $s$ is a nonnegative integer then the $H^{s}$ norm is equivalent to the sum of the $L^{2}$ norms of the derivatives up to order $s$.
(ii) The elements of $H^{s}\left(S^{1}, V\right)$ are continuous for $s>1 / 2$ and, in this case, the inclusion $H^{s}\left(S^{1}, V\right) \rightarrow C^{0}\left(S^{1}, V\right)$ is a compact operator (Lemma A.2.
(iii) Composition with a diffeomorphism of $S^{1}$ induces an automorphism of $H^{s}\left(S^{1}, V\right)$ for every $s \in \mathbb{R}$.
(iv) Multiplication by a smooth complex-valued function on $S^{1}$ induces an automorphism of $H^{s}\left(S^{1}, V\right)$ for every $s \in \mathbb{R}$ (Lemma A.3).
(v) Let $X \subset V$ be open and assume $s>1 / 2$. Then

$$
H^{s}\left(S^{1}, X\right):=\left\{v \in H^{s}\left(S^{1}, V\right): v\left(S^{1}\right) \subset X\right\}
$$

is an open subset of $H^{1}\left(S^{1}, V\right)($ Lemma A.2 ).
(vi) Let $X \subset V$ and $Y \subset W$ be open subsets of finite-dimensional complex Hilbert spaces and $\psi: X \rightarrow Y$ be a smooth map. Assume $s>1 / 2$. Then composition with $\psi$ induces a smooth map from $H^{s}\left(S^{1}, X\right)$ to $H^{s}\left(S^{1}, Y\right)$ (Lemma A.12.

If $E=\bigsqcup_{\theta \in \mathbb{R} / 2 \pi \mathbb{Z}} E_{\theta} \subset S^{1} \times V$ is a smooth (real) subbundle of the trivial bundle then, by (iv), the subspace

$$
H^{s}(E):=\left\{v \in H^{s}\left(S^{1}, V\right): v\left(e^{i \theta}\right) \in E_{\theta} \forall \theta \in \mathbb{R}\right\}
$$

is a closed (real) subspace of $H^{s}\left(S^{1}, V\right)$.
B.2. For every $s>1 / 2$ there is a unique operation which assigns to every compact 1-manifold $\Gamma$ and every smooth manifold $M$ (both without boundary) a real Hilbert manifold $H^{s}(\Gamma, M) \subset C^{0}(\Gamma, M)$ satisfying the following axioms.
(a) If $\Gamma=S^{1}$ and $M$ is an open subset of a complex vector space then $H^{s}(\Gamma, M)$ is as above.
(b) If $\psi: M \rightarrow M^{\prime}$ is a smooth map then $\gamma \in H^{s}(\Gamma, M) \Rightarrow \psi \circ \gamma \in H^{s}\left(\Gamma, M^{\prime}\right)$ and the resulting map $\psi_{*}: H^{s}(\Gamma, M) \rightarrow H^{s}\left(\Gamma, M^{\prime}\right)$ is smooth.
(c) If $\phi: \Gamma^{\prime} \rightarrow \Gamma$ is a diffeomorphism then $\gamma \in H^{s}\left(\Gamma^{\prime}, M\right) \Rightarrow \gamma \circ \phi \in H^{s}(\Gamma, M)$ and the resulting map $\phi^{*}: H^{s}\left(\Gamma^{\prime}, M\right) \rightarrow H^{s}(\Gamma, M)$ is smooth.
(d) If $\Gamma$ is the disjoint union of $\Gamma_{1}$ and $\Gamma_{2}$ then the map $\gamma \mapsto\left(\gamma\left|\Gamma_{1}, \gamma\right| \Gamma_{2}\right)$ is a diffeomorphism from $H^{s}(\Gamma, M)$ to $H^{s}\left(\Gamma_{1}, M\right) \times H^{s}\left(\Gamma_{2}, M\right)$.
The Hilbert manifold structure on $H^{s}(\Gamma, M)$ is given by the exponential maps $H^{s}\left(\gamma^{*} T M\right) \rightarrow H^{s}(\Gamma, M)$ along the smooth maps $\gamma: \Gamma \rightarrow M$. If $M$ is a complex manifold so is $H^{s}(\Gamma, M)$.
B.3. Let $X$ be a compact surface with smooth boundary, $M$ be a smooth manifold, and for each integer $k \geq 2$ let $H^{k}(X, M)$ denote the space of maps from $X$ to $M$ with $k$ derivatives in $L^{2}$. The elements of $H^{k}(X, M)$ are continuous and a well known construction, analogous to the one sketched in B.2, equips $H^{k}(X, M)$ with a smooth Hilbert manifold structure which is a complex Hilbert manifold structure when $M$ is a complex manifold. In particular, the space of $H^{k}$ sections of a vector bundle over $X$ is a Hilbert space. There are various ways of defining a smooth Hilbert manifold structure on the space $H^{s}(X, M)$ when $s$ is a real number greater than 1 , but we shall avoid these spaces. This is why many of our earlier theorems begin with the hypothesis "Let $s+1 / 2$ be an integer".

Theorem B.4. Let $X$ be a compact Riemann surface with boundary $\Gamma:=\partial X$ and $E \rightarrow$ $X$ be a complex vector bundle. Denote the complex structure on $X$ by $j$ and the complex structure on $E$ by J. Fix an integer $k=s+1 / 2 \geq 1$.
(i) There is a constant $c>0$ (depending continuously on $j$ an $J$ ) such that

$$
\|\xi\|_{H^{s}(\Gamma)} \leq c\|\xi\|_{H^{s+1 / 2}(X)}
$$

for every $\xi \in \Omega^{0}(X, E)$.
(ii) Assume that $X$ is connected and $\Gamma \neq \emptyset$. Let $D: \Omega^{0}(X, E) \rightarrow \Omega^{0,1}(X, E)$ be a real linear Cauchy-Riemann operator. Then there is a constant $c>0$ (depending continuously on $j, J$, and $D$ ) such that

$$
\|\xi\|_{H^{s+1 / 2}(X)} \leq c\left(\|D \xi\|_{H^{s-1 / 2}(X)}+\|\xi\|_{H^{s}(\Gamma)}\right)
$$

for every $\xi \in \Omega^{0}(X, E)$.
Proof. These estimates are well known and it is not necessary to assume that $s+1 / 2$ is an integer. We include a proof because we could not find an explicit reference for (ii) in the literature. Assertion (i) is proved by the same argument. Both assertions are easy for sections supported in the interior of $X$. To prove them in general we first consider the case where $X=[0,1] \times S^{1}$ is an annulus with the standard complex structure. Fix a complex (not necessarily holomorphic) trivialization of $E$ over the annulus.

As a warmup we prove (i) for any real number $s \geq 1 / 2$. Denote the inner product on $H^{s}\left(S^{1}, \mathbb{C}^{n}\right)$ by

$$
\langle\xi, \eta\rangle_{s}:=\sum_{n \in \mathbb{Z}}(1+|n|)^{2 s}\left\langle\xi_{n}, \eta_{n}\right\rangle
$$

where $\xi\left(e^{i \theta}\right)=\sum_{n \in \mathbb{Z}} \xi_{n} e^{i n \theta}, \eta\left(e^{i \theta}\right)=\sum_{n \in \mathbb{Z}} \eta_{n} e^{i n \theta}$. Then, for all $\xi, \eta \in C^{\infty}\left(S^{1}, \mathbb{C}^{n}\right)$, the Schwarz inequality gives

$$
\left|\langle\xi, \eta\rangle_{s}\right| \leq\|\xi\|_{s-1 / 2}\|\eta\|_{s+1 / 2}
$$

Hence every smooth function $[0,1] \rightarrow C^{\infty}\left(S^{1}, \mathbb{C}^{n}\right): \tau \mapsto \xi(\tau)$ satisfies the inequality

$$
\begin{aligned}
\frac{d}{d \tau}\|\xi(\tau)\|_{s}^{2} & =2\left\langle\partial_{\tau} \xi(\tau), \xi(\tau)\right\rangle_{s} \leq 2\left\|\partial_{\tau} \xi(\tau)\right\|_{s-1 / 2}\|\xi(\tau)\|_{s+1 / 2} \\
& \leq\left\|\partial_{\tau} \xi(\tau)\right\|_{s-1 / 2}^{2}+\|\xi(\tau)\|_{s+1 / 2}^{2}
\end{aligned}
$$

Integrating this inequality gives

$$
\|\xi(1)\|_{s}^{2} \leq \int_{0}^{1}\left(\left\|\partial_{\tau} \xi(\tau)\right\|_{s-1 / 2}^{2}+\|\xi(\tau)\|_{s+1 / 2}^{2}\right) d \tau \leq\|\xi\|_{H^{s+1 / 2}\left([0,1] \times S^{1}\right)}
$$

whenever $\xi(0)=0$. The last inquality uses the asumption $s \geq 1 / 2$. This proves (i).
We prove (ii). The operator $D$ has the form

$$
D \xi=\frac{1}{2}\left(\partial_{\tau} \xi+i \partial_{\theta} \xi+S \xi\right) d s+\frac{1}{2}\left(\partial_{\theta} \xi-i \partial_{\tau} \xi-i S \xi\right) d t
$$

where $S:[0,1] \times S^{1} \rightarrow \operatorname{End}_{\mathbb{R}}\left(\mathbb{C}^{n}\right)$. Assume first that $S \equiv 0$ and define

$$
f:=\partial_{\tau} \xi+i \partial_{\theta} \xi
$$

We think of $f$ and $\xi$ as functions from $[0,1]$ to $H^{s}\left(S^{1}, \mathbb{C}^{n}\right)$. Consider the decomposition

$$
H^{s}\left(S^{1}, \mathbb{C}^{n}\right)=E^{-} \oplus E^{0} \oplus E^{+}
$$

where $E^{0} \cong \mathbb{C}^{n}$ denotes the space of constant functions and

$$
E^{ \pm}:=\operatorname{closed} \operatorname{span}\left\{e^{i n \theta}: \pm n>0\right\}
$$

The components of an element $\xi \in H^{s}\left(S^{1}, \mathbb{C}^{n}\right)$ with respect to this decomposition will be denoted by $\xi^{-}, \xi^{0}, \xi^{+}$. Note that $e^{i n \theta}$ is an eigenfunction of the operator $A:=-i \partial_{\theta}$ with eigenvalue $n$ and hence

$$
\left\langle\xi^{+}, A \xi^{+}\right\rangle_{s} \geq \frac{1}{2}\left\|\xi^{+}\right\|_{s+1 / 2}^{2}, \quad\left\langle\xi^{-}, A \xi^{-}\right\rangle_{s} \leq-\frac{1}{2}\left\|\xi^{-}\right\|_{s+1 / 2}^{2}
$$

Since $\partial_{\tau} \xi=A \xi+f$ we have

$$
\begin{aligned}
\frac{d}{d \tau}\left\|\xi^{+}(\tau)\right\|_{s}^{2} & =2\left\langle\partial_{\tau} \xi^{+}(\tau), \xi^{+}(\tau)\right\rangle_{s}=2\left\langle A \xi^{+}(\tau)+f^{+}(\tau), \xi^{+}(\tau)\right\rangle_{s} \\
& \geq\left\|\xi^{+}(\tau)\right\|_{s+1 / 2}^{2}-2\left\|f^{+}(\tau)\right\|_{s-1 / 2}\left\|\xi^{+}(\tau)\right\|_{s+1 / 2} \\
& \geq \frac{1}{2}\left\|\xi^{+}(\tau)\right\|_{s+1 / 2}^{2}-2\left\|f^{+}(\tau)\right\|_{s-1 / 2}^{2}
\end{aligned}
$$

Integrating this inequality gives

$$
\begin{equation*}
\int_{0}^{1}\left\|\xi^{+}(\tau)\right\|_{s+1 / 2}^{2} d \tau \leq 4 \int_{0}^{1}\left\|f^{+}(\tau)\right\|_{s-1 / 2}^{2} d \tau+2\left\|\xi^{+}(1)\right\|_{s}^{2} \tag{60}
\end{equation*}
$$

Similarly,

$$
\begin{equation*}
\int_{0}^{1}\left\|\xi^{-}(\tau)\right\|_{s+1 / 2}^{2} d \tau \leq 4 \int_{0}^{1}\left\|f^{-}(\tau)\right\|_{s-1 / 2}^{2} d \tau+2\left\|\xi^{-}(0)\right\|_{s}^{2} \tag{61}
\end{equation*}
$$

and, since $\xi^{0}(\tau)=\xi^{0}(0)+\int_{0}^{\tau} f^{0}(\sigma) d \sigma$, we have

$$
\begin{equation*}
\int_{0}^{1}\left\|\xi^{0}(\tau)\right\|_{s+1 / 2}^{2} d \tau \leq 2 \int_{0}^{1}\left\|f^{0}(\tau)\right\|_{s-1 / 2}^{2} d \tau+2\left\|\xi^{0}(0)\right\|_{s}^{2} \tag{62}
\end{equation*}
$$

(The three norms agree on $E^{0}$.) Combining the inequalities 60-62 we obtain

$$
\begin{equation*}
\int_{0}^{1}\|\xi(\tau)\|_{s+1 / 2}^{2} d \tau \leq 4\left(\int_{0}^{1}\|f(\tau)\|_{s-1 / 2}^{2} d \tau+\|\xi(0)\|_{s}^{2}+\|\xi(1)\|_{s}^{2}\right) \tag{63}
\end{equation*}
$$

Now assume $k:=s+1 / 2$ is an integer. We prove by induction that

$$
\begin{equation*}
\int_{0}^{1}\left\|\partial_{\tau}^{\nu} \xi(\tau)\right\|_{H^{k-v}\left(S^{1}\right)}^{2} d \tau \leq c_{\nu}\left(\|f\|_{H^{k-1}\left([0,1] \times S^{1}\right)}^{2}+\|\xi(0)\|_{s}^{2}+\|\xi(1)\|_{s}^{2}\right) \tag{64}
\end{equation*}
$$

for $v=0,1, \ldots, k$. For $v=0$ this is with $c_{0}=4$. Assuming that 64 has been established for some integer $v \in\{0, \ldots, k-1\}$, we use the inequality

$$
\begin{aligned}
\left\|\partial_{\tau}^{v+1} \xi\right\|_{H^{k-v-1}\left(S^{1}\right)} & =\left\|\partial_{\tau}^{v}(A \xi+f)\right\|_{H^{k-v-1}\left(S^{1}\right)} \\
& \leq\left\|\partial_{\tau}^{v} \xi\right\|_{H^{k-v}\left(S^{1}\right)}+\left\|\partial_{\tau}^{v} f\right\|_{H^{k-v-1}\left(S^{1}\right)}
\end{aligned}
$$

to obtain (64) with $v$ replaced by $v+1$. This completes the induction. Now sum (64) for $v=0,1, \ldots, k$ to obtain the estimate in part (ii) for the case $S=0$ and $X=[0,1] \times S^{1}$. In the case where $S \neq 0$ and $X$ is a general compact Riemann surface we deduce, using partitions of unity and what we have already proved, that

$$
\begin{equation*}
\|\xi\|_{H^{s+1 / 2}(X)} \leq c\left(\|D \xi\|_{H^{s-1 / 2}(X)}+\|\xi\|_{H^{s-1 / 2}(X)}+\|\xi\|_{H^{s}(\Gamma)}\right) \tag{65}
\end{equation*}
$$

for some constant $c>0$ and every smooth section $\xi \in \Omega^{0}(X, E)$. This implies that the operator

$$
H^{s+1 / 2}(E) \rightarrow H^{s-1 / 2}\left(\Lambda^{0,1} T^{*} X \otimes E\right) \times H^{s}(E \mid \Gamma): \xi \mapsto(D \xi, \xi \mid \Gamma)
$$

has a finite-dimensional kernel and a closed image (see [16, Lemma A.1.1]). If $X$ is connected and $\Gamma \neq \emptyset$ then, by unique continuation, this operator is injective and so the term $\|\xi\|_{H^{s-1 / 2}(X)}$ on the right hand side of $\sqrt{65)}$ can be dropped, by the open mapping principle. This proves the theorem.

Acknowledgements. JWR would like to thank Yongbin Ruan for helpful discussions and Ernesto Lupercio and Benardo Uribe for helping him understand the concept of etale groupoid.

[^0]:    1 By the term groupoid, we understand a category all of whose morphisms are isomorphisms.
    2 In what follows, when no confusion can result, we will use the term isomorphism to signify any bijection between sets which preserves the appropriate structures.
    ${ }^{3}$ The reader is cautioned that the term marked Riemann surface is often used with another meaning in the literature.

[^1]:    4 At this point in the discussion this means that the slice is a complex submanifold of $\mathcal{J}(\Sigma)$. After we define the complex structure on the base, a holomorphic slice will be the same thing as the image of a holomorphic section.

[^2]:    5 Also commonly called the isotropy group or stabilizer group.

[^3]:    ${ }^{6}$ For us a manifold is always second countable and Hausdorff, unless otherwise specified.

[^4]:    7 Strictly speaking, the equivalence class is a proper class in the sense of set theory as explained in the appendix of [12] for example. One could avoid this problem by choosing for each stable signature (see Remark 3.5 and 3.8 a "standard marked nodal surface" with that signature and restricting the space of objects of the groupoid $\overline{\mathcal{B}}_{g, n}$ to those having a standard surface as substrate.
