On the singular values of random matrices

Received July 6, 2012

Abstract. We present an approach that allows one to bound the largest and smallest singular values of an \(N \times n\) random matrix with iid rows, distributed according to a measure on \(\mathbb{R}^n\) that is supported in a relatively small ball and for which linear functionals are uniformly bounded in \(L^p\) for some \(p > 8\), in a quantitative (non-asymptotic) fashion. Among the outcomes of this approach are optimal estimates of \(1 \pm c\sqrt{n}/N\) not only in the case of the above mentioned measure, but also when the measure is log-concave or when it is a product measure of iid random variables with “heavy tails”.

Keywords. Singular values, random matrices, heavy tails

1. Introduction

The question of estimating the extremal singular values of a random matrix of the form 
\[
\Gamma = N^{-1/2} \sum_{i=1}^{N} \langle X_i, \cdot \rangle e_i,
\]
that is, of an \(N \times n\) matrix with iid rows, distributed according to a probability measure \(\mu\) on \(\mathbb{R}^n\), has attracted much attention in recent years. As a part of the non-asymptotic approach to the theory of random matrices, obtaining sharp quantitative bounds has many important applications, for example, in asymptotic geometric analysis and in statistics. Instead of listing some of those applications, we refer the reader to [8, 16, 10, 6, 3, 4, 1, 18, 21] and references therein for more details on the history of the problem and its significance. General surveys on the non-asymptotic theory of random matrices may be found in [17, 20].

Our main motivation is to identify assumptions on the measure \(\mu\) that allow one to obtain the typical behavior of the extremal singular values of \(\Gamma\), i.e., assumptions that ensure that for \(N \geq n\), with high probability,
\[
1 - c\sqrt{n}/N \leq s_{\text{min}}(\Gamma) \leq s_{\text{max}}(\Gamma) \leq 1 + c\sqrt{n}/N,
\]
where \(c\) is an absolute constant.
Two particularly interesting cases are when \( \mu \) is an isotropic, log-concave measure [8, 16, 10, 6, 11, 12, 3, 4, 1], and when we have some natural extension of the situation in the asymptotic Bai–Yin theorem [21, 18, 13], formulated below.

**Theorem 1.1** ([7]). Let \( A = A_{N,n} \) be an \( N \times n \) random matrix with independent entries, distributed according to a random variable \( \xi \), for which

\[
\mathbb{E} \xi = 0, \quad \mathbb{E} \xi^2 = 1 \quad \text{and} \quad \mathbb{E} \xi^4 < \infty.
\]

If \( N, n \to \infty \) and the aspect ratio \( n/N \) converges to \( \beta \in (0, 1) \), then

\[
\frac{1}{\sqrt{N}} s_{\min}(A) \to 1 - \sqrt{\beta}, \quad \frac{1}{\sqrt{N}} s_{\max}(A) \to 1 + \sqrt{\beta}
\]

almost surely. Also, without the fourth moment assumption, \( s_{\max}(A)/\sqrt{N} \) is almost surely unbounded.

In a more general setting we assume that the \( n \)-dimensional rows \( X_i, 1 \leq i \leq N \), of the matrix \( \Gamma \) are independent and distributed according to an isotropic probability measure \( \mu \), that is, for every \( t \in S^{n-1} \), \( \mathbb{E} \langle X, t \rangle = 0 \) and \( \mathbb{E} \|\langle X, t \rangle\|_p^2 = 1 \), and that every linear functional has bounded \( p \) moments, i.e. that \( \sup_{t \in S^{n-1}} \|\langle X, t \rangle\|_p \leq \kappa_1 \) (or in the "\( \psi_1 \)-case", that \( \sup_{t \in S^{n-1}} \|\langle X, t \rangle\|_{\psi_1} \leq \kappa_2 \), where \( \|\langle X, t \rangle\|_{\psi_1} = \inf \{s > 0 : \mathbb{E} \exp(|\langle X, t \rangle|/s) \leq 2 \} \).

Note that obtaining the desired bound is equivalent to showing that with high probability,

\[
\sup_{t \in B_2^n} \left| \sum_{i=1}^N \langle X_i, t \rangle^2 - 1 \right| \leq c \sqrt{Nn}, \tag{1.1}
\]

where \( c \) is a constant that depends only on \( p \) and \( \kappa_1 \) (or just on \( \kappa_2 \) in the \( \psi_1 \) case), and \( B_2^n \) is the Euclidean unit ball in \( \mathbb{R}^n \). Since we are interested in CLT-type rates, with a decay of \( \sim 1/\sqrt{N} \), we will focus on the case \( p > 4 \), because for \( p < 4 \), CLT rates are false. Such rates in the non-asymptotic Bai–Yin estimate have recently been established in [13] for \( X = (\xi_i)_{i=1}^n \), where the \( \xi_i \)'s are iid, mean-zero, variance 1 random variables that belong to some \( L_p \) space for \( p > 4 \) (while different rates have been proved there for \( 2 < p \leq 4 \)).

The common threads linking the log-concave and "heavy tails" cases are that in both, the random vector \( X \) is such that with high probability, the Euclidean norm \( \|X\| \) is of the order of \( \sqrt{n} \), and that the linear functionals \( \langle X, t \rangle \) are well behaved: for a log-concave measure we have \( \sup_{t \in S^{n-1}} \|\langle X, t \rangle\|_{\psi_1} \leq \kappa_2 \), while in the "heavy tails" case, \( \sup_{t \in S^{n-1}} \|\langle X, t \rangle\|_{L_p} \leq \kappa_1(p) \).

Having this in mind, the goal of this note is to present a proof of the following result:

**Theorem 1.2.** Let \( \mu \) be an isotropic probability measure on \( \mathbb{R}^n \), let \( N \geq n \) and assume that \( \max_{i \leq N} \|X_i\| \leq C_0(Nn)^{1/4} \). Let \( \kappa_1 \geq 1 \) and let \( k_0 \) be the first integer which satisfies \( k_0 \log(eN/k_0) \geq n \). If \( p > 8 \), \( \sup_{t \in B_2^n} \|\langle t, \cdot \rangle\|_{L_p} \leq \kappa_1 \) and \( 1 \leq \beta \leq c_1 k_0 \), then with \( \mu \)-probability at least

\[
1 - c_2 \left( \frac{1}{N^p} + \exp(-c_3 n) \right).
\]
we have
\[ \sup_{t \in S^{n-1}} \left| \sum_{i=1}^{N} (X_i, t)^2 - 1 \right| \leq c_4 \sqrt{nN}, \]
where \( c_1, c_2, c_3 \) and \( c_4 \) depend only on \( \beta, p, C_0 \) and \( \kappa_1. \)

The proof of Theorem 1.2 can be used to establish the same result in the \( \psi_1 \) case but with a better estimate on the probability. The following theorem already appeared in [3, 4, 2] and recently M. Talagrand found a shorter proof of the same fact [19]. Instead of essentially repeating the proof of Theorem 1.2 we will state at each step the corresponding result in the \( \psi_1 \) case and only sketch the changes required in the proof.

**Theorem 1.3.** Let \( \mu \) be an isotropic probability measure on \( \mathbb{R}^n, \) let \( N \geq n \) and assume that \( \max_{i \leq N} \|X_i\| \leq C_0(nN)^{1/4}. \) If \( \sup_{t \in B^p_2} \|\langle t, \cdot \rangle\|_{\psi_1} \leq \kappa_2, \) then with \( \mu^N \)-probability at least
\[ 1 - 2(\exp(-c_1(nN)^{1/4}) + \exp(-c_1n)), \]
we have
\[ \sup_{t \in S^{n-1}} \left| \sum_{i=1}^{N} (X_i, t)^2 - 1 \right| \leq c_2 \sqrt{nN}, \]
where \( c_1 \) and \( c_2 \) are constants that depend only on \( C_0 \) and \( \kappa_2. \)

As will be explained later, the probability estimate of \( \exp(-cn) \) that appears in Theorems 1.2 and 1.3 is the correct one when \( N \) is larger than \( \exp(c_pn) \) and \( \exp(cn) \) respectively.

The two theorems lead to the desired estimates on the extremal singular values of \( \Gamma \) by a standard argument which we will not present in full. It is well understood that one may replace the \( L_\infty \) condition on \( \|X\| \) with the assumption that \( \Pr(\max_{i \leq N} \|X_i\| \geq t(nN)^{1/4}) \) is well behaved, and the modifications needed in the proofs are minimal. Moreover, in all the examples mentioned above the probability \( \Pr(\max_{i \leq N} \|X_i\| \geq t(nN)^{1/4}) \) is well behaved. Indeed, if \( \mu \) is log-concave then it follows from [15] that \( \Pr(\max_{i \leq N} \|X_i\| \geq t(nN)^{1/4}) \leq 2 \exp(-ct(nN)^{1/4}); \) and if \( \xi \in L_p \) for \( p > 4 \) and \( X = (\xi_i)_{i=1}^{nN} \) has independent coordinates, distributed according to \( \xi, \) one may show that \( \Pr(\max_{i \leq N} \|X_i\| \geq t(nN)^{1/4}) \leq c_p(n/N)^{p/4-1}t^{-p}. \) Since adapting the proof from the \( L_\infty \) assumption to the tail-based one is standard and has appeared in many places, we will not repeat it here.

Theorem 1.2 extends the recent result from [13] beyond the case in which \( X \) has iid coordinates, distributed according to \( \xi \in L_p \) for some \( p > 4, \) and with a considerably easier proof than the original one. On the other hand, it does not cover the range \( 4 < p \leq 8, \) nor can it be extended to a more general context than the case of the Euclidean ball as an indexing set.

Theorem 1.3 was established in [3, 4], but with a weaker probability estimate of \( 1 - 2 \exp(-c_p\sqrt{n}). \) Very recently the original proof from [3, 4] was simplified in [2] and [19], and with the same probability estimate as we obtain here. In fact, several ideas used in both these proofs are essential in ours as well, although we believe that our proof is simpler. Moreover, the proofs from [3, 4] and [2], [19] use the \( \psi_1 \) assumption in an essential way and cannot be extended to the “heavy tails” case.
2. The proof

Throughout, we will denote absolute constants by \( c_1, c_2, \ldots \). Their value may change from line to line. We write \( A \lesssim B \) if there is an absolute constant \( c_1 \) for which \( A \leq c_1 B \). \( A \sim B \) means that \( c_1 A \leq B \leq c_2 A \) for absolute constants \( c_1 \) and \( c_2 \). If the constants depend on some parameter \( r \) we will write \( A \lesssim_r B \) or \( A \sim_r B \). We will denote the Euclidean norm by \( \| \cdot \| \). Finally, if \( (a_n) \) is a sequence, let \( (a^*_{n}) \) be the non-increasing rearrangement of \( (a_n) \).

The proof begins with the following simple observation on a monotone rearrangement of iid random variables. Recall that \( k_0 \) satisfies \( k_0 \log(eN/k_0) \sim n \) if \( \log(eN) \gtrsim n \) and \( k_0 = 1 \) otherwise.

**Lemma 2.1.** Let \( Z_1, \ldots, Z_N \) be iid random variables, distributed according to \( Z \).

1. If \( p > 4 \) and \( C_0, \beta > 0 \), then there exist constants \( c_0, c_1, c_2 \) and \( c_3 \) that depend only on \( p \), \( C_0 \) and \( \beta \) for which the following hold. If \( \| Z \|_L^\infty \leq C_0 (Nn)^{1/4} \) and \( u \geq c_0 \), then
   \[
   \sum_{2^i \leq u k_0} (Z_{2^i}^*)^2 \leq c_1 (1 + u \| Z \|_L^2)^{(Nn)^{1/2}} \text{ with probability at least } 1 - c_2 N^{-\beta},
   \]
   and
   \[
   \sum_{2^i \leq u k_0} (Z_{2^i}^*)^4 \leq c_3 \| Z \|_{p^*}^4 N \text{ with probability at least } 1 - 2 \exp(-c_4 u n).
   \]
   Also, for \( u \geq c_6 \), we have
   \[
   \sum_{2^i = k_0 + 1}^N (Z_{2^i}^*)^4 \leq c_5 u^4 \| Z \|_{p^*}^4 N \text{ with probability at least } 1 - 2 \exp(-c_7 u n).
   \]

2. For the second part, take \( t_i = \| Z \|_{L_p}^{(eN/2^i)^{(1+\epsilon)/p}} = \| Z \|_{L_p}^{(eN/2^i)^{1/4}} \) and let \( \max[2/\epsilon, 1] < u \lesssim (N/k_0)^{1/2} \). Hence, with probability at least
   \[
   1 - \sum_{u k_0 \geq 2^i N} \exp(-2^i \epsilon \log(eN/2^i)) \geq 1 - \exp(-c_1 \epsilon u k_0 \log(eN/k_0)) \geq 1 - \exp(-c_2 u n),
   \]
   \[
   \sum_{2^i \leq u k_0} 2^i (Z_{2^i}^*)^2 \leq \| Z \|_L^{2^{i/2}} 2^i 2^{i/2} \sum_{2^i \leq u k_0} 2^i \alpha_s^2 
   \leq c_9 2^{3i} (Nn)^{i/2} + \| Z \|_{L_p}^{2^{i/2}} \sum_{2^i \leq u k_0} 2^{i/2} \lesssim_{\beta,p} (1 + u^{1/2} \| Z \|_{L_p}^2)(Nn)^{i/2}.
   \]

   For the second part, take \( t_i = \| Z \|_{L_p}^{(eN/2^i)^{(1+\epsilon)/p}} = \| Z \|_{L_p}^{(eN/2^i)^{1/4}} \) and let \( \max[2/\epsilon, 1] < u \lesssim (N/k_0)^{1/2} \). Hence, with probability at least
   \[
   1 - \sum_{u k_0 \geq 2^i N} \exp(-2^i \epsilon \log(eN/2^i)) \geq 1 - \exp(-c_1 \epsilon u k_0 \log(eN/k_0)) \geq 1 - \exp(-c_2 u n),
   \]

   Then
   \[
   \sum_{2^i \leq u k_0} 2^i (Z_{2^i}^*)^2 \leq \| Z \|_L^{2^{i/2}} 2^{i/2} \sum_{2^i \leq u k_0} 2^i \alpha_s^2 
   \leq c_9 2^{3i} (Nn)^{i/2} + \| Z \|_{L_p}^{2^{i/2}} \sum_{2^i \leq u k_0} 2^{i/2} \lesssim_{\beta,p} (1 + u^{1/2} \| Z \|_{L_p}^2)(Nn)^{i/2}.
   \]
we have
\[ \sum_{u k_0 \leq 2 \leq N} 2^s (Z_{u k_0}^*)^4 \lesssim \|Z\|_{L_p}^4 \sum_{u k_0 \leq 2 \leq N} 2^s (eN/2^s)^{4(1+\epsilon)/p} \lesssim_p \|Z\|_{L_p}^4 N. \]

Next, consider the \( \psi_1 \) case. Let \( s_2 \) be the first integer for which \( 2^s \log (eN/2^s) \geq (Nn)^{1/4} \) and assume without loss of generality that \( 2^{s_2} \leq k_0 \). Put \( \alpha_s \sim 1/2^s \) for \( s \leq s_2 \) and let \( \alpha_{s_2} \sim (\log (eN/2^{s_2}))/ (Nn)^{1/4} \) for \( 2^{s_2} \leq 2^s \leq k_0 \). Note that if \( s \leq s_2 \) then
\[ \Pr(Z_{s_2}^* \geq \|Z\| \alpha_s (Nn)^{1/4}) \leq \exp(2^s \log (eN/2^s) - c_1 (Nn)^{1/4}) \leq \exp(-c_2 (Nn)^{1/4}), \]
and if \( 2^{s_2} \leq 2^s \leq k_0 \) then
\[ \Pr(Z_{s_2}^* \geq \|Z\| \alpha_{s_2} (Nn)^{1/4}) \leq \exp(-c_3 2^s \log (eN/2^s)). \]
Since \( k_0 \log^2 (eN/k_0) \lesssim n \log (eN/n) \),
\[ \sum_{2^s \leq k_0} 2^s \alpha_{s_2}^2 \leq \sum_{2^s \leq k_0} 2^{-s} + \frac{2^s \log^2 (eN/2^s)}{(Nn)^{1/2}} \lesssim 1 + \left( \frac{n}{N} \right)^{1/2} \log \left( \frac{eN}{n} \right) \lesssim c_4. \]
Summing the probabilities, it follows that with probability at least \( 1 - 2 \exp(-c_5 (Nn)^{1/4}) \),
\[ \sum_{i=1}^{k_0} (Z_i^*)^2 \lesssim \sum_{2^s \leq k_0} 2^s (Z_{s_2}^*)^2 \lesssim \|Z\|_{\psi_1}^2 \sqrt{Nn}, \]
which proves our first claim in the \( \psi_1 \) case.

Turning to the second part, fix \( u \geq 2 \) and consider \( t_s = u \|Z\| \alpha_s (eN/2^s) \). Observe that \( \Pr(Z_{s_2}^* \geq t_s) \leq \exp(-(u - 1)2^s \log (eN/2^s)) \) and \( k_0 \log (eN/k_0) \sim n \). By summing the probabilities, it is evident that
\[ \sum_{k_0 \leq 2^s \leq N} 2^s (Z_{s_2}^*)^4 \leq u^4 \|Z\|_{\psi_1}^4 \sum_{k_0 \leq 2^s \leq N} 2^s \log^4 (eN/2^s) \lesssim u^4 \|Z\|_{\psi_1}^4 N \]
with probability at least \( 1 - 2 \exp(-c_6 u n) \). \( \square \)

The following corollary uses the same idea as in Lemma 2.1 and we will need it only when \( k_0 > 1 \). To formulate it, fix \( 0 < \gamma < 1 \) and \( \kappa_3 \) to be specified later, let \( \kappa_\ell = \gamma^{\ell} k_0 \) and let \( \ell_0 \) be the first integer satisfying \( k_\ell \log (eN/k_\ell) \leq \kappa_3 (Nn)^{1/4} \). The constants \( \gamma \) and \( \kappa_3 \) will depend only on \( p \) and their value will be specified in the proof of Lemma 2.3 below.

**Corollary 2.2.** There exists a constant \( c_1 \) such that for every \( 0 < \gamma < 1 \) there exists a constant \( c_2 = c_2(\gamma) \) for which the following holds. Let \( p > 4 \) and \( \epsilon = p/4 - 1 \), let \( \ell_1 > 0 \) be any integer for which \( k_{\ell_1} \geq 1 \), and let \( Z_1, \ldots, Z_N \) be iid random variables, distributed according to \( Z \) with \( \|Z\|_p < \infty \). Then, for every \( 0 \leq \ell < \ell_1 \), with probability at least \( 1 - (eN/k_{\ell_1+1})^{-\epsilon k_{\ell+1}} \), we have \( \sum_{j=k_{\ell+1}}^{k_{\ell_1}} (Z_j^*)^2 \lesssim c_1 \|Z\|_{\ell_p} \eta_\ell \), where \( \eta_\ell \sim (Nk_\ell)^{1/4} \).

In particular, \( \sum_{\ell=0}^{\ell_1-1} \eta_\ell \leq c_2 (Nn)^{1/4} \).
Moreover, if $Z_1, \ldots, Z_N$ are iid random variables, distributed according to $Z$ with $\|Z\|_{\psi_1} < \infty$, there exist absolute constants $c_3$, $c_4$ and $c_5$ for which the following holds. Let $\gamma = 1/2$. Then for every $0 \leq \ell < \ell_0$ and $u \geq c_3$, with probability at least $1 - 2 \exp(-c_4u^2 \log(eN/k\ell))$,

$$(\sum_{j=0}^{\ell_0} (Z_j^*)^2)^{1/2} \leq c_5 u \|Z\|_{\psi_1} \bar{\eta}_\ell,$$

where $\sum_{\ell=0}^{\ell_0-1} \bar{\eta}_\ell \leq c_5(Nn)^{1/4}$.

Corollary 2.2 follows from the same argument used in the second parts of the $L_p$ and $\psi_1$ cases in Lemma 2.1, with the choice of $t_k = (eN/k\ell)^{(1+\varepsilon)/p} = (eN/k\ell)^{1/4}$ in the $L_p$ case and $t_k = u \log(eN/k\ell)$ in the $\psi_1$ case, combined with a straightforward calculation.

Next, let us turn to the main ingredient of the proof. Consider $U_k = \{x \in S^{N-1} : |\text{supp}(x)| \leq k\}$ and set $A_k = \sup_{x \in U_k} \|\sum_{i=1}^N a_i X_i\|$. The motivation for studying this quantity is that for every $k \leq N$, $A_k = \sup_{t \in \mathbb{R}_+^k} (\sum_{i=1}^k (X_i, t_i^*)^2)^{1/2}$, but for reasons that will become clear later, we only need to bound $A_{k_0}$.

For every $k$, let $\delta_k$ be determined later and let $\mathcal{N}_k$ be a subset of $B_2^N$ such that for every $x \in \mathbb{R}^N$,

$$\sup_{y \in \mathcal{N}_k} \langle y, x \rangle = (1 - \delta_k) \sup_{z \in U_k} \langle y, x \rangle.$$

It is standard to verify that there is a set $\mathcal{N}_k$ as above of cardinality at most $\exp(k \log(eN/k\delta_k))$.

The main application of Corollary 2.2 is the following lemma.

**Lemma 2.3.** For every $p > 8$, $C_0$, $\kappa_1$ and $\beta > 0$ as in Theorem 1.2, there exist constants $c_1$ and $c_2$ that depend only on $p$, $C_0$, $\kappa_1$ and $\beta$ and for which the following holds. If $I \subset \{1, \ldots, N\}$, then in the $L_p$ case, with $\mu^N$-probability at least $1 - c_1/N^\beta$,

$$\sup_{a \in U_{k_0}} \sup_{b \in U_{k_0}} \left(\sum_{i \in I} a_i X_i, \sum_{i \in I'} b_i X_i\right) \leq c_2(Nn)^{1/4} A_{k_0}.$$

Also, in the $\psi_1$ case, there are constants $c_3$ and $c_4$ that depend only on $C_0$ and $\kappa_2$, for which, with $\mu^N$-probability at least $1 - 2 \exp(-c_3(Nn)^{1/4})$,

$$\sup_{a \in U_{k_0}} \sup_{b \in U_{k_0}} \left(\sum_{i \in I} a_i X_i, \sum_{i \in I'} b_i X_i\right) \leq c_4(Nn)^{1/4} A_{k_0}.$$

Again, we will restrict ourselves to the case in which $k_0 > 1$, since the modifications needed when $k_0 = 1$ are minor.

**Proof.** Let us begin with the $L_p$ case. Consider the sets $U_{k_0}$ as above and let

$$B_{k_0} = \sup_{a \in U_{k_0}} \sup_{b \in U_{k_0}} \left(\sum_{i \in I} a_i X_i, \sum_{i \in I'} b_i X_i\right).$$
The main observation is that for every $0 \leq \ell \leq \ell_1$,

$$
\rho_{k_{\ell}} B_{k_{\ell}} \leq B_{k_{\ell+1}} + \sup_{b \in \mathcal{N}_{k_{\ell}}} \left( \sum_{i=k_{\ell+1}+1}^{k_{\ell}} \left( \left( \sum_{j \in I^c} b_j X_j, X_i \right)^* \right)^2 \right)^{1/2}
+ \sup_{a \in \mathcal{N}_{k_{\ell+1}}} \left( \sum_{j=k_{\ell+1}+1}^{k_{\ell}} \left( \left( \sum_{i \in I} a_i X_i, X_j \right)^* \right)^2 \right)^{1/2}
$$

(2.1)

where $\rho_{k_{\ell}} = (1 - \delta_{k_{\ell}})(1 - \delta_{k_{\ell+1}})$ and $\ell_1$ will be defined later.

Indeed, fix $a \in U_{k_{\ell}}$ and let $Z_{a,i} = \langle \sum_{j \in I} a_i X_j, X_j \rangle$. By the definition of $\mathcal{N}_{k_{\ell}}$,

$$
\sup_{b \in U_{k_{\ell}}} \sum_{j \in I^c} b_j Z_{a,j} \leq (1 - \delta_{k_{\ell}})^{-1} \sup_{b \in \mathcal{N}_{k_{\ell}}} \sum_{j \in I^c} b_j Z_{a,j}.
$$

Note that

$$
\sup_{a \in U_{k_{\ell}}} \sup_{b \in \mathcal{N}_{k_{\ell}}} \sum_{j \in I^c} b_j Z_{a,j} = \sup_{b \in \mathcal{N}_{k_{\ell}}} \sup_{a \in U_{k_{\ell}}} \sum_{i \in I} a_i \left\langle X_i, \sum_{j \in I^c} b_j X_j \right\rangle = (*)
$$

setting $W_{b,i} = \langle X_i, \sum_{j \in I^c} b_j X_j \rangle$ for $i \in I$, it is evident that

$$
(*) \leq \sup_{a \in U_{k_{\ell}}} \left( \sum_{i=1}^{k_{\ell}} (W^*_{a,i})^2 \right)^{1/2}
\leq \sup_{a \in U_{k_{\ell+1}}} \sup_{b \in \mathcal{N}_{k_{\ell}}} \left( \sum_{i \in I} a_i X_i, \sum_{j \in I^c} b_j X_j \right) + \sup_{a \in \mathcal{N}_{k_{\ell+1}}} \left( \sum_{i=k_{\ell+1}+1}^{k_{\ell}} (W^*_{a,i})^2 \right)^{1/2}.
$$

Replacing $U_{k_{\ell+1}}$ by $\mathcal{N}_{k_{\ell+1}}$ and repeating the argument used above for the first term (while reversing the roles of $a$ and $b$) proves (2.1).

Since $|\mathcal{N}_{k_{\ell}}| \leq \exp(k_\ell \log(eN/k_\ell \delta_\ell))$, and using the independence of $(X_j)_{j \in I^c}$ and $(X_i)_{i \in I}$, a straightforward application of Corollary 2.2 shows that with probability at least

$$
1 - 2 \exp(-(p/4 - 1)k_{\ell+1} \log(eN/k_{\ell+1}) + k_\ell \log(eN/k_\ell \delta_\ell)) = (**),
$$

for every $b \in \mathcal{N}_{k_{\ell}}$ and every $a \in \mathcal{N}_{k_{\ell+1}}$ we have

$$
\left( \sum_{i=k_{\ell+1}+1}^{k_{\ell}} \left( \sum_{j \in I^c} b_j X_j, X_i \right)^* \right)^2 \leq (cNk_{\ell})^{1/4} A_{k_0}
$$

and

$$
\left( \sum_{j=k_{\ell+1}+1}^{k_{\ell}} \left( \sum_{i \in I} a_i X_i, X_j \right)^* \right)^2 \leq (cNk_{\ell})^{1/4} A_{k_0}.
$$
Since \( p/4 > 2 \), there is \( \gamma < 1 \) for which \((p/4 - 1)\gamma > 1\). Thus, for \( p > 8 \) there are \( \gamma \), \( c_1 \) and \( c_2 \) that depend only on \( p \), and for which one may take \( \delta_{k_\ell} = (k_\ell/N)^{c_1} \), satisfying

\[ (***) \geq 1 - 2 \exp(-c_2k_{\ell+1} \log(eN/k_{\ell+1})). \]

Now let \( \ell_1 \) be the largest integer \( \ell \) for which both \( k_\ell - k_{\ell+1} > 1 \) and

\[ \sum_{j=0}^{\ell} \exp(-c_2k_{j+1} \log(eN/k_{j+1})) \leq N^{-\beta}. \]

Therefore, \( \ell_1 \) is the first integer satisfying \((p/4 - 2)k_\ell \log(eN/k_\ell) \leq \kappa_3 \beta \log N \) for an appropriate choice of \( \kappa_3 \).

Observe that there is a constant \( c_3 \) that depends only on \( p \) for which \( \prod_{t=0}^{\ell_1} (1 - \delta_{k_t})^2 \geq c_3 \). Hence, repeating this dimension reduction procedure up to \( \ell = \ell_1 \) and then applying the “large coordinates” estimate from Lemma 2.1 for \( B_{k_1} \) (while observing that \( k_{\ell_1} \leq k_0 \)) concludes the proof.

The proof in the \( \psi_1 \) case is similar—only with a different termination point for the dimension reduction process: \( k_{\ell_0} \) instead of \( k_{\ell_1} \). We omit the details of this case.

Note that in the proof of the previous lemma we needed that \( p/4 - 1 > 1 \). This is the only point in our proof where the fact \( p > 8 \) is required.

**Theorem 2.4.** Under the assumptions of Theorem 1.2, there are constants \( c_1 \) and \( c_2 \), depending only on \( \beta \), \( p \), \( C_0 \) and \( k_1 \), for which \( A_{k_0} \leq c_2(Nn)^{1/4} \) with probability at least \( 1 - c_1N^{-\beta} \).

Under the assumptions of Theorem 1.3, there are constants \( c_3 \) and \( c_4 \), depending only on \( C_0 \) and \( k_2 \), for which \( A_{k_0} \leq c_4(Nn)^{1/4} \) with probability at least \( 1 - 2 \exp(-c_3(Nn)^{1/4}) \).

**Proof.** We will only present a proof in the \( \ell_P \) case, as the \( \psi_1 \) case has an almost identical proof. Clearly, for every \( a \in U_{k_0} \), \( \| \sum_{i=1}^{N} a_i X_i \|^2 = \sum_{i \neq j} a_i a_j \langle X_i, X_j \rangle + \sum_{i=1}^{N} a_i^2 \| X_i \|^2 \), and since \( \| a \| \leq 1 \), the second term is at most \( \max_{i \leq N} \| X_i \|^2 \leq C_0(Nn)^{1/2} \).

To bound the first term, let \( (\varepsilon_i)_{i=1}^{N} \) be independent Bernoulli random variables. Note that

\[ \mathbb{E}_{\varepsilon} \sum_{i \neq j} (1 + \varepsilon_i)(1 - \varepsilon_j)a_i a_j \langle X_i, X_j \rangle = \sum_{i \neq j} a_i a_j \langle X_i, X_j \rangle, \]

and thus it suffices to control

\[
\sup_{a \in U_{k_0}} \mathbb{E}_{\varepsilon} \sum_{i \neq j} (1 + \varepsilon_i)(1 - \varepsilon_j)a_i a_j \langle X_i, X_j \rangle \\
\leq \mathbb{E}_{\varepsilon} \sup_{a \in U_{k_0}} \sum_{i \neq j} (1 + \varepsilon_i)(1 - \varepsilon_j)a_i a_j \langle X_i, X_j \rangle = \mathbb{E}_{\varepsilon} H((\varepsilon_i)_{i=1}^{N}, (X_i)_{i=1}^{N}).
\]

Observe that if \( L_\varepsilon = \{ i : \varepsilon_i = 1 \} \) then

\[ H((\varepsilon_i)_{i=1}^{N}, (X_i)_{i=1}^{N}) = 4 \sup_{a \in U_{k_0}} \left\{ \sum_{i \in L_\varepsilon} a_i X_i, \sum_{j \in L_\varepsilon^c} a_j X_j \right\} \]

for every realization of \( (\varepsilon_i)_{i=1}^{N} \).
Fix \( (\varepsilon_i)_{i=1}^N \), then
\[
H((\varepsilon_i)_{i=1}^N, (X_i)_{i=1}^N) \lesssim \sup_{a \in \mathcal{U}_0} \sup_{b \in \mathcal{U}_0} \left\langle \sum_{i \in I_a} a_i X_i, \sum_{j \in I_j} b_j X_j \right\rangle.
\]

By Lemma 2.3, if \( p > 8 \), then \( H((\varepsilon_i)_{i=1}^N, (X_i)_{i=1}^N) \lesssim_p (Nn)^{1/4} A_{k_0} \) with \( \mu_k \)-probability at least \( 1 - \varepsilon N^{-\beta} \). Thus, by a Fubini argument, there exists a set \( B \subset \Omega^N \) of \( \mu_k \)-probability at least \( 1 - c_1 N^{-\beta/2} \) on which \( H((\varepsilon_i)_{i=1}^N, (X_i)_{i=1}^N) \lesssim_p (Nn)^{1/4} A_{k_0} \) with \( \mu_k \)-probability at least \( 1 - c_2 N^{-\beta/2} \). Hence, for every \( (X_i)_{i=1}^N \in B \),
\[
\mathbb{E}_x H((\varepsilon_i)_{i=1}^N, (X_i)_{i=1}^N) \lesssim_p A_{k_0} (Nn)^{1/4} + N^{-\beta/2} \sup_{a \in \mathcal{U}_0} \left\langle \sum_{i \neq j} a_i a_j (X_i, X_j) \right\rangle
\]
\[
\lesssim_{p,c_0} A_{k_0} (Nn)^{1/4} + N^{-\beta/2} (A_{k_0}^2 + (Nn)^{1/2}),
\]
where the last inequality follows from the Cauchy–Schwarz inequality and the definition of \( A_{k_0} \). Therefore, on \( B \), if \( \beta > 0 \) and \( N \) is large enough, then \( A_{k_0}^2 \lesssim_{p,c_0} A_{k_0} (Nn)^{1/4} + (Nn)^{1/2} \), and the claim follows.

The final observation we need is a straightforward application of Lemma 2.1 to the random variables \( Z_i = \langle X, t \rangle \), for vectors \( t \) in a 1/2-net in \( B_2^N \).

**Lemma 2.5.** Under the assumptions of Theorem 1.2 there exist constants \( c_1, c_2, c_3, c_4, c_5 \) depending only on \( k_1 \) for which the following holds. If \( \mathcal{N} \) is a maximal 1/2-separated subset of \( B_2^N \) then with probability at least \( 1 - 2 \exp(-c_1 n) \),
\[
\sup_{i \in \mathcal{N}} \left( \sum_{i=k_0+1}^N \left| \langle X_i, t \rangle \right|^4 \right)^{1/2} \leq c_2 \sqrt{N}.
\]

Moreover, under the assumptions of Theorem 1.3, there exist absolute \( c_4 \) and \( c_5 \) depending only on \( k_2 \) for which with probability at least \( 1 - 2 \exp(-c_3 n) \),
\[
\sup_{i \in \mathcal{N}} \left( \sum_{i=k_0+1}^N \left| \langle X_i, t \rangle \right|^4 \right)^{1/2} \leq c_5 \sqrt{N}.
\]

**Proof of Theorem 1.2.** Let \( \mathcal{N} \) be a maximal 1/2-separated subset of \( B_2^N \) and let \( \mathcal{C} \) be the intersection of the events from Theorem 2.4 and Lemma 2.5. Note that on \( \mathcal{C} \), with \( \mu_k \)-probability at least \( 1 - 2 \exp(-c_1 n) \),
\[
\sup_{i \in B_2^N} \left| \sum_{i=1}^N \varepsilon_i \langle X_i, t \rangle \right|^2 \lesssim_{c_0, p} \sqrt{Nn}.
\]

Indeed, let \( c_3 \) be the constant from Lemma 2.5, fix \( i, t' \in \mathcal{N} \) and let \( J \) be the union of the sets of the largest \( c_3 k_0 \) coordinates of \( \langle \langle X_i, t \rangle \rangle_{i=1}^N \) and \( \langle \langle X_i, t' \rangle \rangle_{i=1}^N \). By Hoeffding’s inequality, for every \( v > 0 \), with \( \mu_k \)-probability at least \( 1 - 2 \exp(-c_4 v^2) \),
\[
\left| \sum_{i=1}^{N} \xi_i(X_i, t)(X_i, t') \right| \lesssim \sum_{i \in J} |\langle X_i, t \rangle(\langle X_i, t \rangle, t')| + v \left( \sum_{i \in J} \langle X_i, t \rangle^2(\langle X_i, t \rangle, t')^2 \right)^{1/2} \leq 2c_3 \left( \sum_{i=1}^{k_0} \langle (X_i, t) \rangle^2 \right)^{1/2} \left( \sum_{i=1}^{\kappa_0} \langle (X_i, t) \rangle^2 \right)^{1/2} + v \left( \sum_{i=1}^{N} \langle (X_i, t) \rangle^4 \right)^{1/4} \left( \sum_{i=1}^{N} \langle (X_i, t) \rangle^4 \right)^{1/4} \lesssim A_{k_0}^2 + v \sqrt{N}.
\]

Let \( v \sim \sqrt{n} \). Since \( |N| \leq 5^n \), there is a set \( D \subset \{-1, 1\}^N \) of \( \mu_2^N \)-probability at least \( 1 - 2 \exp(-c_5 n) \) on which (2.3) holds for any pair \( t, t' \) taken from \( N \times N \). Since each \( t \in B_2^n \) can be written as \( \sum_{i=1}^{\infty} \beta_i t_i \) with \( \beta_i \leq 2^{-i} \) and \( t_i \in N \), on \( D \) we have

\[
\sup_{t \in B_2^n} \left| \sum_{i=1}^{N} \xi_i(X_i, t) \right|^2 \lesssim (Nn)^{1/2} \sum_{i,j=1}^{\infty} 2^{-i} 2^{-j} \lesssim (Nn)^{1/2},
\]

with constants that depend on \( k_0, C_0, p \) and \( \beta \). The assertion now follows from a standard application of a variation of the Giné–Zinn symmetrization theorem [9] (see also [13, §5.3]).

\( \Box \)

The proof of 1.3 follows the same lines and we will not present the details.

Finally, let us point out that the estimate on the probability in Theorem 1.2 (and in Theorem 1.3 as well) is of the right order when \( N \geq e^{cp_n} \), where \( e_p > 0 \) is a constant that depends only on \( p \); observe that in that range, the dominant term in the probability estimate is \( e^{-cn} \).

Indeed, set \( A = \sup_{t \in B_2^n} |N^{-1/2} \sum_{i=1}^{N} (\langle X_i, t \rangle^2 - 1)| \), and note that for any fixed \( t \in S^{n-1} \), \( \Pr(A > cn^{1/2}) \geq \Pr(|N^{-1/2} \sum_{i=1}^{N} (\langle X_i, t \rangle^2 - 1)| > cn^{1/2}) \). By a variant of the Berry–Esseen theorem (see [14, Theorem 2.2]) it follows that

\[
\Pr\left( \left| N^{-1/2} \sum_{i=1}^{N} (\langle X_i, t \rangle^2 - 1) \right| > cn^{1/2} \right) - \Pr(|g| > cn^{1/2}) \lesssim \frac{1}{N^2},
\]

where \( \alpha \) depends only on \( p \) (and is positive for any \( p > 4 \)), and \( g \) is a standard Gaussian variable. Hence, under our assumptions and for those very large values of \( N \), it is evident that \( \Pr(A > cn^{1/2}) > (1/2) \exp(-c_1 n) \).

2.1. Final remarks

Many of the ideas used in the proof of Theorem 1.2 can actually be traced back to Bourgain [8], who studied the log-concave case and obtained estimates on the random variables \( \max_{|t| \leq m} \| \sum_{i \in J} X_i \| \) using a combination of self-bounding and decoupling arguments. This led to a bound on the non-increasing rearrangement of vectors \( ((\langle X_i, t \rangle))_{i=1}^{N} \), uniformly for \( t \in B_2^n \).

In [11], similar uniform bounds were obtained in the more general, empirical processes setup, and under a \( \psi_1 \)-tail assumption; that is, estimates on the quantity \( \sup_{f \in F} \max_{|t| = m} \| \sum_{i \in E} f(X_i) \| \) for a general class of functions \( F \) with a bounded di-
On the singular values of random matrices

ameter in $L_{\psi_1}$. In both cases, the quantity that was estimated was not the right one for the problem at hand, and thus the approach resulted in slightly suboptimal estimates on $\sup_{f \in F} | \sum_{i=1}^N f^2(X_i) - \mathbb{E}f^2 | $.

Bourgain’s method was extended and improved in [3, 4], in which the parameters $A_m$ were introduced. This, combined with the correct level of truncation ($(Nn)^{1/4}$ rather than $n^{1/2}$) were the main ingredients in the solution of the log-concave case, though only with the probability estimate of $1 - 2 \exp(-c\sqrt{n})$.

At the same time, it was noted in [12] that one may use a chaining argument to control $\sup_{f \in F} \max_{i|m} | \sum_{i \in I} f^2(X_i) |^{1/2}$ for a general class of functions $\mathcal{F}$ with a bounded diameter in $L_{\psi_1}$. Of course, when considering $\mathcal{F} = \{ (t, \cdot) : t \in \mathbb{B}^2 \}$, this quantity is just $A_m$. This approach was extended further in [13], allowing one to control the empirical process $\sup_{f \in F} | \sum_{i=1}^N f^2(X_i) - \mathbb{E}f^2 | $ for classes that are only bounded in $L_p$ rather than in $L_{\psi_1}$.

To see why our proof follows the same ideas as [12, 13], one should observe that the key point in [12, 13] was to study the fine structure of the random coordinate projection $V = \{(f(X_i))_{i=1}^N : f \in F \}$, and then use this structure to handle the Bernoulli process indexed by $V^2$ (without reverting to the Gaussian process indexed by the same set!). To that end, one obtains information on the monotone rearrangement of each “link” $( (\pi_{s+1} f - \pi_s f)(X_i) )_{i=1}^N$ in the chain given by the admissible sequence $(F_i)$, where at each step, one balances the cardinality of the set of links and $\binom{N}{k}$. In this way, one may obtain uniform information on the $k$ largest coordinates of $( (\pi_{s+1} f - \pi_s f)(X_i) )_{i=1}^N$ for that value of $k$. Moreover, these $k$ largest coordinates are controlled in terms of a “global” notion of complexity of $\mathcal{F}$ (e.g. the $\gamma_2$ functional), while the smaller coordinates are estimated in the same way we did here—using tail estimates on each random variable $(\pi_s f - \pi_{s+1} f)(X)$.

Unlike the general case, here, the structure is rather simple because $\mathbb{B}^2$ is both large and very regular. In particular, one should not expect chaining to have any advantage over the union bound—which can be viewed as “one-step chaining”, or alternatively, chaining that starts at a set of cardinality $\exp(cn)$. Having this in mind, our proof follows the path mentioned above: the balance should be between the “cardinality” of $\mathbb{B}^2$, i.e. $\exp(cn)$, and $\binom{N}{k}$, which is precisely the definition of $k_0$. What happens on the “large” $k_0$ coordinates (i.e. $A_{k_0}$) depends on a “global” property, $\max_{i \leq N} \| X_i \|$ (Theorem 2.4), while the “small” coordinates are estimated using only individual tail estimates (Lemma 2.5).
