Brill–Noether loci for divisors on irregular varieties

Received February 21, 2012 and in revised form September 12, 2012

Abstract. We take up the study of the Brill–Noether loci $W^r(L,X) := \{ \eta \in \text{Pic}^0(X) \mid h^0(L \otimes \eta) \geq r + 1 \}$, where $X$ is a smooth projective variety of dimension $> 1$, $L \in \text{Pic}(X)$, and $r \geq 0$ is an integer.

By studying the infinitesimal structure of these loci and the Petri map (defined in analogy with the case of curves), we obtain lower bounds for $h^0(K_D)$, where $D$ is a divisor that moves linearly on a smooth projective variety $X$ of maximal Albanese dimension. In this way we sharpen the results of [Xi] and we generalize them to dimension $> 2$.

In the 2-dimensional case we prove an existence theorem: we define a Brill–Noether number $\rho(C,r)$ for a curve $C$ on a smooth surface $X$ of maximal Albanese dimension and we prove, under some mild additional assumptions, that if $\rho(C,r) \geq 0$ then $W^r(C,X)$ is nonempty of dimension $\geq \rho(C,r)$.

Inequalities for the numerical invariants of curves that do not move linearly on a surface of maximal Albanese dimension are obtained as an application of the previous results.

Keywords. Irregular variety, Brill–Noether theory, Albanese dimension

1. Introduction

The classical Brill–Noether theory studies the loci

$$W^r_d(C) := \{ L \in \text{Pic}(C) \mid \deg L = d, \ h^0(L) \geq r + 1 \},$$

where $C$ is a smooth projective curve of genus $g \geq 2$. We refer the reader to [ACGH] for a comprehensive treatment of this beautiful topic and to [ACG] for further information. We only recall here that all the theory revolves around the Brill–Noether number $\rho(g,r,d) = g - (r + 1)(r + g - d)$: if $\rho(g,r,d) \geq 0$ then $W^r_d(C)$ is not empty, and if $\rho(g,r,d) > 0$ then $W^r_d(C)$ is connected of dimension $\geq \rho(g,r,d)$. In addition, if $C$ is general in moduli then $\dim W^r_d(C) = \rho(g,r,d)$.

Mathematics Subject Classification (2010): 14C20, 14J29, 14H51
Several possible generalizations of this theory have been investigated in the past years, the most studied being the case in which divisors of fixed degree are replaced by stable vector bundles of fixed rank and degree on the smooth curve $C$ (see [GT] for a recent survey). Generalizations to some varieties of dimension $> 1$ have been considered by several people (see for instance [DL], [H], [Le]).

Moreover, Brill–Noether type loci for higher-dimensional varieties occur naturally in the theory of deformations, Hilbert schemes, Picard schemes and Fourier–Mukai transforms, but usually not as the main object of study. In [CM] the case of vector bundles on an arbitrary smooth projective variety is considered under the assumption that all the cohomology groups of degree $> 1$ vanish. In [Kl1] the Brill–Noether loci are defined in great generality for relative subschemes of any codimension of a family of projective schemes, but the theory is developed only in the case of linear series on smooth projective curves. Any concrete theory of special divisors, like for instance existence theorems, seems impossible in such generality.

Here we take up what seems to us the most straightforward generalization of the classical theory of linear series on curves, namely the case of line bundles on an arbitrary projective variety. In this setup, Brill–Noether loci are a special instance of cohomological support loci, whose study has been started in [GL1], [GL2], focusing on the case of topologically trivial line bundles, and has been extended and refined in the context of rank one local systems (see for instance [DPS]). However, our point of view and that of [GL1], [GL2] are different, since we look for lower bounds on the dimension of these loci rather than for upper bounds.

Let us now summarize the content of the paper. Given a projective variety $X$, a line bundle $L \in \text{Pic}(X)$ and an integer $r \geq 0$, we set $W^r(L, X) := \{ \eta \in \text{Pic}^0(X) \mid h^0(L \otimes \eta) \geq r + 1\}$. First we recall the natural scheme structure on $W^r(L, X)$ and, by analysing it, we show that, if $X$ has maximal Albanese dimension (i.e., it has generically finite Albanese map) and $D$ is an effective divisor contained in the fixed part of $|K_X|$, then $0 \in W(D, X)$ is an isolated point (Corollary 3.5).

Then we focus on two special cases: (a) singular projective curves and (b) smooth surfaces of maximal Albanese dimension. In case (a) we assume that $X$ is a connected reduced projective curve and, since in general $\text{Pic}^0(X)$ is not an abelian variety, we study the intersection of $W^r(L, X)$ with a compact subgroup $T \subseteq \text{Pic}^0(X)$ of dimension $t$. We define the Brill–Noether number $\rho(t, r, d) := t - (r + 1)(p_a(C) - d + r)$, where $d := \deg L$.

In this set-up we prove the exact analogue of the existence theorem of Brill–Noether theory under a technical assumption on $T$ (Theorem 5.1, cf. also Remark 5.2). We do not consider here the very important theory of the compactifications of the Brill–Noether loci of singular curves and the theory of limit linear series as treated by many authors (see, for instance, [Gi, EH, AI, EK, Cap, ACG]; in particular [ACG] has a complete bibliography). Our reason is that we are interested in line bundles coming from a smooth complete variety via restriction, and these are naturally parametrized by a compact subgroup.

Theorem 5.1 is a key step in our approach to case (b): we combine it with the generic vanishing theorem of Green and Lazarsfeld to obtain an analogue of the existence theorem of Brill–Noether theory. Given a curve $C$ on a surface $S$ with irregularity $q > 1$, we consider the image $T$ of the natural map $\text{Pic}^0(S) \rightarrow \text{Pic}^0(C)$. If this map has finite kernel
and we take \( L = \mathcal{O}_C(C) \), then the Brill–Noether number introduced above can be written as \( \rho(C, r) := q - (r + 1)(p_a(C) - C^2 + r) \). (For \( r = 0 \) we write simply \( \rho(C) \).)

For surfaces without irrational pencils of genus \( g > 1 \) and reduced curves \( C \) all of whose components have positive self-intersection, we prove that if \( \rho(C, r) > \rho(C, r) \), then \( W^r(C, S) \) is nonempty of dimension \( \geq \min(q, \rho(C, r)) \), and that for \( \rho(C, r) = 1 \) the same statement holds under an additional assumption. In the specific case \( r = 0 \) and under the same hypotheses we are also able to show that \( C \) actually moves algebraically in a family of dimension \( \geq \min(q, \rho(C)) \). For the precise statement see Theorem 6.2. We remark that the assumptions on the Albanese map and on the structure of \( V^1 \) in these results are quite mild (see Remark 6.3 and Section 2).

A second theme of the paper, strictly interwoven with the analysis of Brill–Noether loci, is the study of the restriction map \( r_D : H^0(K_X) \to H^0(K_X|D) \), where \( X \) is a smooth variety of maximal Albanese dimension and \( D \subset X \) is an effective divisor whose image via the Albanese map \( a : X \to \text{Alb}(X) \) generates \( \text{Alb}(X) \). In Proposition 4.6 we establish a uniform lower bound for the rank of \( r_D \) under the only assumption that \( D \) is not contained in the ramification locus of the Albanese map (this is also one of the ingredients of the proof of the Brill–Noether type result for surfaces). Then we show how one can improve on this bound if the tangent space to \( W^0(D, X) \) at 0 has positive dimension (Proposition 4.9); in order to do this we introduce and study, in analogy with the case of curves, the Petri map \( H^1(D) \otimes H^0(K_X - D) \to H^0(K_X) \). If \( h^0(D) > 1 \), a lower bound for the rank of \( r_D \) gives immediately a lower bound for \( h^0(K_D) \) (Corollaries 4.7 and 4.10): in this way we extend to arbitrary dimension the main result of [Xi], which treats the case in which \( X \) is a surface and \( D \) is a general fiber of a fibration \( X \to \mathbb{P}^1 \).

All the previous results are applied in §7 to the study of curves on a surface of general type \( S \) with \( q(S) := h^0(K_S) > 1 \) that is not fibered onto a curve of genus \( g > 1 \). More precisely, we give inequalities for the numerical invariants of a curve \( C = \sum_i C_i \) of \( S \) such that \( C_i^2 > 0 \) for all \( i \) and \( h^0(C_i) = 1 \) (Corollary 7.4); in the special case in which \( p_a(C) \leq 2q(S) - 2 \) we obtain a stronger inequality and a lower bound on the codimension of \( W^0(C, S) \) in \( \text{Pic}^0(S) \) (Corollary 7.6). Note that, apart from the case \( p_a(C) = q(S) \) (classified in [MPP1]), the question of the existence on a surface of general type \( S \) of curves \( C \) with \( C^2 > 0 \) and \( p_a(C) \leq 2q(S) - 2 \) is, as far as we know, completely open. Finally, we prove a result (Proposition 7.7) that relates the fixed locus of the paracanonical system of \( S \) to the ramification divisor of the Albanese map.

In §8 we collect several examples in order to illustrate the phenomena that occur for Brill–Noether loci on surfaces and to clarify to what extent the results that we obtain are optimal. We also pose some questions: in our opinion, the most important of these is whether a statement analogous to Theorem 6.2 holds if one replaces the effective divisor \( C \) by, say, an ample line bundle, and whether a similar statement holds in arbitrary dimension. The main difficulty here is that, while in the case of curves the cohomology of a family of line bundles of fixed degree is computed by a complex with only two terms, in the case of a variety of dimension \( n \) one has to deal with a complex of length \( n + 1 \). Hence the negativity of Picard sheaves, which has been established for projective varieties of any dimension (cf. [La, 6.3.C and 7.2.15]), does not suffice alone to prove nonemptiness results for Brill–Noether loci.
In the surface case the method of restriction to curves and the use of generic vanishing theorems overcome the cohomological problem. We are aware however that usually curves lying on surfaces are not general in the sense of Brill–Noether theory, hence, although the existence theorem 6.2 is sharp, one cannot expect that the Brill–Noether number computes precisely the dimension of the Brill–Noether locus in most cases. In fact, in view of the complexity of the geometry and of the topology of irregular surfaces (even the geographical problem has not been solved yet, cf. [MP]), it is somewhat surprising that a single numerical invariant, such as the Brill–Noether number, can give a definite existence result for continuous families of effective divisors on surfaces. Our methods are also useful for attacking problems in classification theory and questions about curves on surfaces, as illustrated in [MPP1] and in Section 7 of this paper.

In addition, the use of generic vanishing combined with the infinitesimal analysis in Sections 3 and 4 shows the importance of the Petri map in the higher-dimensional case. We are convinced that the methods of the present paper together with the use of some fine obstruction theory as in [MPP2] will give some striking new results in the theory of continuous families of divisors on irregular varieties, which is ultimately Brill–Noether theory.

**Notation and conventions.** We work over the complex numbers. All varieties are assumed to be complete. We do not distinguish between divisors on smooth varieties and the corresponding line bundles, and we denote linear equivalence by ≡.

Let $X$ be a smooth projective variety. We denote as usual by $\chi(X)$ the Euler characteristic of $O_X$, by $p_g(X)$ the geometric genus $h^0(X, K_X)$ and by $q(X)$ the irregularity $h^0(X, \Omega_X^1)$. We denote by albdim$(X)$ the dimension of the image of the Albanese map $a: X \rightarrow \text{Alb}(X)$. As usual, a fibration of $X$ is a surjective morphism with connected fibers $X \rightarrow Y$, where $Y$ is a variety with dim $Y < \text{dim } X$. We say that $X$ has an irrational pencil of genus $g > 0$ if it admits a fibration $X \rightarrow B$ onto a smooth curve of genus $g > 0$.

If $D$ is an effective divisor of a smooth variety $X$ we denote by $p_a(D)$ the arithmetic genus $\chi(K_D) − 1$, where $K_D$ is the canonical divisor of $D$. In particular, if dim $X = 2$ and $D$ is a nonzero effective divisor (a curve) then by the adjunction formula the arithmetic genus of $D$ of $S$ is $p_a(D) = (K_S D + D^2)/2 + 1$; the curve $D$ is said to be $m$-connected if, given any decomposition $D = A + B$ of $D$ with $A, B > 0$, one has $AB \geq m$.

Given a product of varieties $V_1 \times \cdots \times V_n$ we denote by $\text{pr}_i$ the projection onto the $i$-th factor.

### 2. Preliminaries on irregular varieties

We recall some by now classical results on irregular varieties that are used repeatedly throughout the paper.

#### 2.1. Albanese dimension and irregular fibrations

Let $X$ be a smooth projective variety of dimension $n$. The Albanese dimension albdim$(X)$ is defined as the dimension of the image of the Albanese map of $X$; in particular, $X$ has
maximal Albanese dimension if its Albanese map is generically finite onto its image and it is of Albanese general type if in addition \( q(X) > n \). For a normal variety \( Y \), we define the Albanese variety \( \text{Alb}(Y) \) and all the related notions by considering any smooth projective model of \( Y \).

An irregular fibration \( f : X \to Y \) is a morphism with positive-dimensional connected fibers onto a normal variety \( Y \) with \( \text{albdim } Y = \dim Y > 0 \); the map \( f \) is called an Albanese general type fibration if in addition \( Y \) is of Albanese general type. If \( \dim Y = 1 \), then \( Y \) is a smooth curve of genus \( b > 0 \); in that case, \( f \) is called an irrational pencil of genus \( b \), and it is an Albanese general type fibration if and only if \( b > 1 \).

Notice that if \( q(X) \geq n \) and \( X \) has no Albanese general type fibration, then \( X \) has maximal Albanese dimension.

The so-called generalized Castelnuovo–de Franchis Theorem (see [Cat, Thm. 1.14] and Ran [Ra]) shows how the existence of Albanese general type fibrations is detected by the cohomology of \( X \):

**Theorem 2.1** (Catanese, Ran). The smooth projective variety \( X \) has an Albanese general type fibration \( f : X \to Y \) with \( \dim Y \leq k \) if and only if there exist independent 1-forms \( \omega_0, \ldots, \omega_k \in H^0(\Omega^1_X) \) such that
\[
\omega_0 \wedge \omega_1 \wedge \cdots \wedge \omega_k = 0 \in H^0(\Omega^{k+1}_X).
\]

So in particular the existence of irrational pencils of genus > 1 is equivalent to the existence of two independent 1-forms \( \alpha, \beta \in H^0(\Omega^1_X) \) such that \( \alpha \wedge \beta = 0 \).

### 2.2. Generic vanishing

Let \( X \) be a projective variety of dimension \( n \) and let \( L \in \text{Pic}(X) \); the generic vanishing loci, or Green–Lazarsfeld loci, are defined as \( V^i(X) := \{ \eta \mid h^i(\eta) > 0 \} \subseteq \text{Pic}^0(X) \), \( i = 0, \ldots, n \). They have been an object of intensive study since the groundbreaking papers [GL1], [GL2], [Be2], [Be3] and [Si]:

**Theorem 2.2.** Let \( X \) be a smooth projective variety. Then:

(i) if \( X \) has maximal Albanese dimension, then \( V^1(X) \) is a proper closed subset of \( \text{Pic}^0(X) \) whose components are translates by torsion points of abelian subvarieties;

(ii) if \( X \) has no irrational pencil of genus > 1, then \( \dim V^1(X) \leq 1 \) and \( 0 \in V^1(X) \) is an isolated point.

### 3. Brill–Noether loci

In this section we recall the definition of Brill–Noether loci and some general facts on their geometry. The scheme structure and the tangent space to a Brill–Noether locus have been described in several contexts; however, for clarity’s sake we choose to spell out and prove the properties we need. We close the section by proving some properties of the ramification divisor of the Albanese map and of the fixed divisor of the canonical system of a variety of maximal Albanese dimension (Proposition 3.4 and Corollary 3.5).
Let $X$ be a projective variety and let $L ∈ \text{Pic}(X)$. For $r ≥ 0$ we define the Brill–Noether locus

$$W^r(L, X) := \{ η ∈ \text{Pic}^0(X) \mid h^0(L ⊗ η) ≥ r + 1 \}.$$ 

If $T ⊆ \text{Pic}^0(X)$ is a subgroup, we set $W^r_T(L, X) := W^r(L, X) ∩ T$. For $r = 0$ we write $W(L, X)$ instead of $W^0(L, X)$.

**Remark 3.1.** When $X$ is a smooth curve, Brill–Noether loci are a very classical object of study (cf. [ACGH, Chs. III–V]). The definition we give here is slightly different from the classical one, which consists in fixing a class $λ ∈ \text{NS}(X)$ and defining the Brill–Noether locus as

$$W^r_λ(X) := \{ M ∈ \text{Pic}^λ(X) \mid h^0(M) ≥ r + 1 \},$$

where $\text{Pic}^λ(X)$ denotes the preimage of $λ$ via the natural map $\text{Pic}(X) → \text{NS}(X)$. Of course, if $λ$ is the class of $L$ in $\text{NS}(X)$, then $W^r(L, X)$ is mapped isomorphically onto $W^r_λ(X)$ by the translation by $L ∈ \text{Pic}(X)$. Our choice of definition is motivated by technical reasons that become apparent, for instance, in the proof of Theorem 6.2.

By the semicontinuity theorem (cf. [Mu, p. 50]) Brill–Noether loci are closed in $\text{Pic}^0(X)$. In fact, they are a particular case of cohomological support loci introduced in [GL1, §1].

The scheme structure of $W^r(L, X)$ is described by following the approach of [Kl1].

Our point of view differs slightly from [Kl1] in that we consider line bundles rather than subschemes.

We recall the following consequence of Grothendieck duality:

**Lemma 3.2.** Let $X$ be a projective variety of dimension $n$, let $L ∈ \text{Pic}(X)$ and let $P$ be a Poincaré line bundle on $X × \text{Pic}^0(X)$. Then there exists a coherent sheaf $Q$ on $\text{Pic}^0(X)$, unique up to canonical isomorphism, such that:

(i) for every coherent sheaf $M$ on $\text{Pic}^0(X)$ there is a canonical isomorphism

$$\text{Hom}_{\text{Pic}^0(X)}(Q, M) ≅ \text{pr}_{2*}(P ⊗ \text{pr}^*_1 L ⊗ \text{pr}^*_2 M);$$

(ii) if $X$ is Gorenstein, then $Q ≅ \text{R}^n\text{pr}_{2*}(\text{pr}^*_1(K_X - L) ⊗ P^\vee)$.

**Proof.** (i) Follows by applying [EGAIII2, Thm. 7.7.6] to $\text{pr}_2^*: X × \text{Pic}^0(X) → \text{Pic}^0(X)$ and to the sheaf $P ⊗ \text{pr}^*_1 L$.

(ii) By (i) it is enough to show that for every coherent sheaf $M$ on $\text{Pic}^0(X)$ there is a canonical isomorphism

$$\text{Hom}_{\text{Pic}^0(X)}(\text{R}^n\text{pr}_{2*}(\text{pr}^*_1(K_X - L) ⊗ P^\vee), M) ≅ \text{pr}_{2*}(P ⊗ \text{pr}^*_1 L ⊗ \text{pr}^*_2 M).$$

If $X$ is a Gorenstein variety, then $\text{pr}^*_1 ω_X$ is the relative dualizing sheaf for the morphism $\text{pr}_2^*: X × \text{Pic}^0(X) → \text{Pic}^0(X)$ and, since $X$ is Cohen–Macaulay, the required functorial isomorphism exists by [Kl2, Thm. 21].

By Lemma 3.2 (i), a point $η ∈ \text{Pic}^0(X)$ belongs to $W^r(L, X)$ iff $\dim_C(Q ⊗ \mathcal{O}(η)) ≥ r + 1$; hence we give $W^r(L, X)$ the $r$-th Fitting subscheme structure associated with the sheaf $Q$. Notice that, since $P$ is determined up to tensoring with $\text{pr}^*_2 M$ for $M$ a line bundle on
Pic\(^0\)(X), \(Q\) is also determined up to tensoring with \(M\); however, \(Q\) and \(Q \otimes M\) have the same Fitting subschemes, hence our definition is independent of the choices made.

Given \(\eta \in \text{Pic}\(^0\)(X)\), we identify as usual the tangent space to \(\text{Pic}\(^0\)(X)\) at the point \(\eta\) with \(H^1(\mathcal{O}_X)\); then, generalizing the case when \(X\) is a curve, we have the following description of the Zariski tangent space to \(W^r(L, X)\).

**Proposition 3.3.** Let \(r \geq 0\) be an integer, let \(X\) be a projective variety, let \(L \in \text{Pic}(X)\) and let \(\eta \in W^r(L, X)\). Then:

(i) if \(\eta \in W^{r+1}(L, X)\), then \(T_{\eta}W^r(L, X) = H^1(\mathcal{O}_X)\);

(ii) if \(\eta \notin W^{r+1}(L, X)\), then \(T_{\eta}W^r(L, X)\) is the kernel of the linear map \(H^1(\mathcal{O}_X) \to \text{Hom}(H^0(X, L + \eta), H^1(X, L + \eta))\) induced by cup product.

**Proof.** Let \(Q\) be the coherent sheaf of Lemma 3.2. As usual, we denote by \(\mathbb{C}[^\epsilon]\) the algebra of dual numbers. We regard an element \(v \in H^1(\mathcal{O}_X)\) as a morphism \(v: \text{spec} \mathbb{C}[^\epsilon] \to \text{Pic}\(^0\)(X)\) mapping the closed point of \(\text{spec} \mathbb{C}[^\epsilon]\) to \(\eta\) and we denote by \(Q_v\) the pull back of \(Q\) via \(v\). By the functorial properties of Fitting ideals, \(v\) is in the tangent space to \(W^r(L, X)\) iff the \(r\)-th Fitting ideal of \(Q_v\) as a \(\mathbb{C}[^\epsilon]\)-module vanishes. Set \(m := h^0(X, L + \eta)\). By the definition of \(Q\) (Lemma 3.2), there is an isomorphism \(\text{Hom}_{\mathbb{C}[\epsilon]}(Q_v, \mathbb{C}) \cong H^0(X, L + \eta)\); it is not hard to show that there is an isomorphism \(Q_v \cong \mathbb{C}[\epsilon]^{m-l} \oplus \mathbb{C}^l\) for some \(0 \leq l \leq m\). Hence \(Q_v\) has a presentation by an \(m \times l\) matrix with \(\epsilon\) on the diagonal and 0 elsewhere. A direct computation shows that the \(r\)-th Fitting ideal is 0 iff either \(m > r + 1\), or \(m = r + 1\) and \(l = 0\). In particular, this proves claim (i) and we may assume from now on that \(m = r + 1\).

Denote by \(L_v\) the pull back of \(\mathcal{P} \otimes \text{pr}_1^* L\) to \(X_\epsilon := X \times \text{spec} \mathbb{C}[^\epsilon]\). The condition \(l = 0\) is equivalent to the surjectivity of the map \(\text{Hom}_{\mathbb{C}[\epsilon]}(Q_v, \mathbb{C}[\epsilon]) \to \text{Hom}_{\mathbb{C}[\epsilon]}(Q_v, \mathbb{C})\). By Lemma 3.2, we have canonical isomorphisms

\[
\text{Hom}_{\mathbb{C}[\epsilon]}(Q_v, \mathbb{C}[\epsilon]) \cong H^0(X_v, L_v), \quad \text{Hom}_{\mathbb{C}[\epsilon]}(Q_v, \mathbb{C}) \cong H^0(X, L + \eta).
\]

So \(v\) is tangent to \(W^r(L, X)\) at \(\eta\) iff the restriction map \(H^0(X_v, L_v) \to H^0(X, L + \eta)\) is surjective. On the other hand, this map is part of the long cohomology sequence associated with the extension

\[
0 \to L + \eta \xrightarrow{v} L_v \to L + \eta \to 0,
\]

hence it is surjective iff the coboundary map \(H^0(X, L + \eta) \to H^1(L + \eta)\) vanishes. Since it is well known that the latter map is given by cupping with \(v\), statement (ii) follows. \(\square\)

As an application of Proposition 3.3 we prove the following:

**Proposition 3.4.** Let \(X\) be a smooth projective variety such that \(n := \dim X = \text{albdim } X\) and let \(R\) be the ramification divisor of the Albanese map of \(X\); if \(0 < Z \leq R\) is a divisor and \(s \in H^0(\mathcal{O}_X(Z))\) is a section that defines \(Z\), then:

(i) the map \(H^1(\mathcal{O}_X) \to H^1(\mathcal{O}_X(Z))\) is injective;

(ii) if \(h^0(Z) = 1\), then \(H^0(Z|_Z) = 0\) and \(0 \in W(Z, X)\) is an isolated point (with reduced structure).
Proof. (i) Denote by $\Lambda$ the image of the map $\bigwedge^n H^0(\Omega^1_X) \to H^0(K_X)$; the divisor $R$ is the fixed part of the linear subsystem $|\Lambda| \subseteq |K_X|$. 

Assume for contradiction that $v \in H^1(O_X)$ is a nonzero vector such that $s \cup v = 0$; then, since $Z \leq R$, we have $t \cup v = 0$ for every $t \in \Lambda$.

By Hodge theory there exists a nonzero $\beta \in H^0(1_X)$ such that $v = \bar{\beta}$ and the condition $t \cup \bar{\beta}$ is equivalent to $t \wedge \bar{\beta}$ being an exact form: $t \wedge \bar{\beta} = d\phi$. Let now $x \in X$ be a point such that $\beta(x) \neq 0$ and such that the differential of the Albanese map at $x$ is injective. Then we can find $\alpha_1, \ldots, \alpha_{n-1} \in H^0(1_X)$ such that $\bar{\alpha}_1, \ldots, \bar{\alpha}_{n-1}, \beta$ span the cotangent space $T^*_x X$. Hence the form $t := \alpha_1 \wedge \cdots \wedge \alpha_{n-1} \wedge \beta$ is nonzero at $x$ and therefore $t \wedge t \neq 0$ and $(-i)^n \int_X t \wedge t > 0$. On the other hand, we have

$$\int_X t = \pm \int_X (t \wedge \bar{\beta}) \wedge \bar{\alpha}_1 \wedge \cdots \wedge \bar{\alpha}_{n-1} = \int_X d(\phi \wedge \bar{\alpha}_1 \wedge \cdots \wedge \bar{\alpha}_{n-1}) = 0,$$

a contradiction. So $H^1(O_X) \cup_X H^1(O_X(R))$ is injective.

(ii) By (i) and by Proposition 3.3, the tangent space to $W(Z, X)$ at $0$ is zero, hence $\{0\}$ with reduced structure is a component of $W(Z, X)$. The vanishing of $H^0(Z|Z)$ also follows from (i) by taking cohomology in the usual restriction sequence $0 \to O_X \to O_X(Z) \to O_Z(Z) \to 0$. 

\[\Box\]

**Corollary 3.5.** Let $X$ be a smooth projective variety such that $n := \dim X = \text{albdim } X$ and let $Z > 0$ be a divisor contained in the fixed part of $|K_X|$. Then $H^0(Z|Z) = 0$ and $0 \in W(Z, X)$ is an isolated point.

**Proof.** As usual, let $R$ denote the ramification divisor of the Albanese map of $X$. Since $Z$ is contained in the fixed part of $|K_X|$, we have $Z \subseteq R$ and $h^0(Z) = 1$. So the claim follows by Proposition 3.4. \[\Box\]

### 4. Restriction maps

In this section we consider a smooth projective variety $X$ of maximal Albanese dimension and an effective divisor $D \subseteq X$ and we establish lower bounds for the rank of the restriction map

$$r_D: H^0(K_X) \to H^0(K_X|D),$$

and for the corank of the residue map

$$\text{res}_D: H^0(K_X + D) \to H^0(K_D).$$

Such bounds, besides being intrinsically interesting, can be used to give lower bounds for the arithmetic genus of divisors moving in a positive-dimensional linear system (Corollaries 4.7 and 4.10).

More precisely, we give three inequalities. The first two (Proposition 4.6) are uniform bounds for the rank of $r_D$ and the corank of $\text{res}_D$ under the assumptions that $D$ is irreducible, not contained in the ramification locus of the Albanese map $a: X \to \text{Alb}(X)$,
and \(a(D)\) generates \(\text{Alb}(X)\). This is one of the ingredients in the proof of Theorem 6.2, which is our main result on the structure of Brill–Noether loci in the case of surfaces.

The third one (Proposition 4.9) is based on the infinitesimal analysis of the Brill–Noether locus \(W^r(D, X)\) carried out in §3: the bound that we obtain is stronger than that of Proposition 4.6 but it requires further assumptions.

4.1. Preliminary results

The main goal of this section is to prove Proposition 4.5, which is the key result that enables us to obtain the inequalities of §4.2.

We start by listing some well known facts of linear algebra:

**Lemma 4.1** (Hopf lemma). Let \(U, V, W\) be complex vector spaces of finite dimension and let \(f: U \otimes V \to W\) be a linear map. If \(\ker f\) does not contain any nonzero simple tensor \(u \otimes v\), then \(\text{rk} f \geq \dim U + \dim V - 1\).

**Lemma 4.2.** Let \(V, W\) be complex vector spaces of finite dimension and let \(f: \bigwedge^k V \to W\) be a linear map. If \(\ker f\) does not contain any nonzero simple tensor \(v_1 \wedge \cdots \wedge v_k\), then \(\text{rk} f \geq k(\dim V - k) + 1\).

**Lemma 4.3** (ker/coker lemma). Let \(V, W\) be complex vector spaces of finite dimension and let \(f, g: V \to W\) be linear maps. If \(\text{rk}(f + tg) \leq \text{rk} f\) for every \(t \in \mathbb{C}\), then \(g(\ker f) \subseteq \text{Im} f\).

The next result is possibly also known, but since it is less obvious we give a proof for completeness.

**Lemma 4.4.** Let \(V, W\) be complex vectors spaces of finite dimension and set \(q := \dim V\). Let \(\phi: \bigwedge^2 V \to W\) be a linear map such that:

(a) for every \(0 \neq v \in V\), there exists \(w \in V\) such that \(\phi(v \wedge w) \neq 0\);

(b) if \(\phi(v \wedge w) = \phi(v \wedge u) = 0\) and \(v \neq 0\), then \(\phi(u \wedge w) = 0\).

Then:

(i) \(\dim \phi(V) \geq q - 1\);

(ii) there exists \(v \in V\) such that the restriction of \(\phi\) to \(v \wedge V\) is injective.

**Proof.** We observe first of all that (i) follows from (ii), hence it is enough to prove (ii).

For every \(v \in V\) we let \(k_v: V \to W\) be the linear map defined by \(x \mapsto \phi(v \wedge x)\), and we let \(U(v)\) be the kernel and \(S(v)\) be the image of \(k_v\). Of course \(v \in U(v)\), and for \(v \neq 0\) the assumptions give:

1. \(U(v) \subseteq V\);
2. \(U(v) = U(v') \Leftrightarrow v' \in U(v) \setminus \{0\}\).
Claim (ii) is equivalent to the existence of a vector $v \in V$ such that $U(v)$ is 1-dimensional. Choose $v$ with $m := \dim U(v)$ minimal; notice that $0 < m < q$. For any vector $u \in V$ and any $t \in \mathbb{C}$ the map $k_u + tk_v$ has rank $\leq q - m$; by Lemma 4.3 we have $k_u(U(v)) \subseteq S(v)$. Hence if $\phi(v' \wedge v) = 0$, then for any $u \in V$ there exists $h \in V$ such that

$$k_u(v') = \phi(u \wedge v') = \phi(v \wedge h) = k_v(h).$$

Since $k_u(v') = -k_v(u)$, it follows that for every $v' \in U(v)$ we have $S(v') \subseteq S(v)$; since $U(v) = U(v')$ by (2), it follows that $S(v) = S(v')$. Let now $L \subset V$ be a subspace such that $V = U(v) \oplus L$. Then for every $0 \neq v' \in U(v)$, $k_v$ restricts to an isomorphism $h_{v'} : L \to S(v)$. If we fix bases for $L$ and $S(v)$, this isomorphism is represented by an invertible matrix of order $q - m > 0$, whose entries depend linearly on $v'$. Then taking determinants one obtains a homogeneous polynomial of degree $q - m$ that has no zeros on $\mathbb{P}(U(v))$. Since we are working over an algebraically closed field, this is possible only if $\dim U(v) = 1$.

Claim (ii) is equivalent to the existence of a vector $v \in V$ such that $U(v)$ is 1-dimensional. Choose $v$ with $m := \dim U(v)$ minimal; notice that $0 < m < q$. For any vector $u \in V$ and any $t \in \mathbb{C}$ the map $k_u + tk_v$ has rank $\leq q - m$; by Lemma 4.3 we have $k_u(U(v)) \subseteq S(v)$. Hence if $\phi(v' \wedge v) = 0$, then for any $u \in V$ there exists $h \in V$ such that

$$k_u(v') = \phi(u \wedge v') = \phi(v \wedge h) = k_v(h).$$

Since $k_u(v') = -k_v(u)$, it follows that for every $v' \in U(v)$ we have $S(v') \subseteq S(v)$; since $U(v) = U(v')$ by (2), it follows that $S(v) = S(v')$. Let now $L \subset V$ be a subspace such that $V = U(v) \oplus L$. Then for every $0 \neq v' \in U(v)$, $k_v$ restricts to an isomorphism $h_{v'} : L \to S(v)$. If we fix bases for $L$ and $S(v)$, this isomorphism is represented by an invertible matrix of order $q - m > 0$, whose entries depend linearly on $v'$. Then taking determinants one obtains a homogeneous polynomial of degree $q - m$ that has no zeros on $\mathbb{P}(U(v))$. Since we are working over an algebraically closed field, this is possible only if $\dim U(v) = 1$.

Given a vector bundle $E$ on a variety $X$ and a finite-dimensional subspace $V \subseteq H^0(X, E)$, for any integer $k \geq 0$ we denote by $\psi_k : \bigwedge^k V \to H^0(X, \bigwedge^k E)$ the natural map. Here is the main result of this section:

**Proposition 4.5.** Let $X$ be an irreducible variety, let $E$ be a rank $n$ vector bundle on $X$. Assume that there exists a subspace $V \subseteq H^0(X, E)$ of dimension $q$ that generates $E$ generically. Then the map $\psi_n : \bigwedge^n V \to H^0(X, \det E)$ has rank $\geq q - n + 1$.

**Proof.** The proof is by induction on the rank $n$ of $E$, the case $n = 1$ being trivial.

Up to restricting to a Zariski open set, we may assume that $X$ is affine and that $E$ generates $V$.

Consider first the map $\psi_2 : \bigwedge^2 V \to W := H^0(X, \bigwedge^2 E)$. Since $\psi_2$ satisfies the assumptions of Lemma 4.4, there exist a section $s \in V$ such that $\psi_2(s \wedge t) = 0$ if and only if $t = ks$ for some $k \in \mathbb{C}$. Up to replacing $X$ by an open subset, we may assume that $s$ vanishes nowhere on $X$, hence there is a short exact sequence

$$0 \to \mathcal{O}_X \xrightarrow{s} E \to E' \to 0,$$

with $E'$ a rank $n - 1$ vector bundle. We denote by $V' \subseteq H^0(X, E')$ the image of $V$; the subspace $V'$ has dimension $q - 1$ and generates $E'$ on $X$, hence by the inductive assumption the map $\psi'_{n-1} : \bigwedge^{n-1} V' \to H^0(X, \det E')$ has rank $\geq (q - 1) - (n - 1) + 1 = q - n + 1$.

The sequence (4.1) induces an isomorphism $\det E \to \det E'$ and the induced map $H^0(X, \det E) \to H^0(X, \det E')$ maps $\text{Im} \psi_n$ to a subspace containing $\text{Im} \psi'_{n-1}$. Hence $\text{rk} \psi_n \geq \text{rk} \psi'_{n-1} \geq q - n + 1$.

4.2. Uniform bounds

Here we use the results of §4.1 to bound the rank of the map $r_D : H^0(K_X) \to H^0(K_X[1])$ and the corank of the residue map $\text{res}_D : H^0(K_X + D) \to H^0(K_D)$, where $D$ is an effective divisor of an irregular variety $X$. 

Proposition 4.6. Let $X$ be a smooth projective variety with albdim $X = \dim X = n$ and let $D > 0$ be an irreducible divisor of $X$ such that the image of $D$ via the Albanese map $a : X \to \text{Alb}(X)$ generates $\text{Alb}(X)$. Assume that $D$ is not contained in the ramification divisor of $a$. Then, letting $q := q(X)$:

(i) the rank of $r_D : H^0(K_X) \to H^0(K_X|D)$ is $\geq q - n + 1$;
(ii) the corank of $\text{res}_D : H^0(K_X + D) \to H^0(K_D)$ is $\geq q - n + 2$.

Proof. (i) The inequality follows from Proposition 4.5 by taking $E = \Omega^1_X|D$ and $V = i^*H^0(X, \Omega^1_X)$, where $i : D \to X$ is the inclusion.

(ii) Consider the short exact sequence $0 \to K_X \to K_X + D \to K_D \to 0$. Taking cohomology, we see that the corank of $\text{res}_D$ is equal to the rank of the coboundary map $\partial : H^0(K_D) \to H^1(K_X)$ or, taking duals, to the rank of $\partial^* : H^{n-1}(O_X) \to H^{n-1}(O_D)$.

Now let $(X', D')$ be an embedded resolution of $(X, D)$; then there is a commutative diagram

$$
\begin{array}{ccc}
H^{n-1}(O_X) & \longrightarrow & H^{n-1}(O_{X'}) \\
\downarrow \phi & & \downarrow \phi \\
H^{n-1}(O_D) & \longrightarrow & H^{n-1}(O_{D'})
\end{array}
$$

where the top horizontal map is an isomorphism. Hence we may assume without loss of generality that $D$ is smooth.

Then, by Hodge theory, the map $\phi^*$ is the complex conjugate of the natural map $\rho : H^0(\Omega^{n-1}_X) \to H^0(K_D)$. Here we set $E = \Omega^1_D$ and $V = i^*H^0(\Omega^1_X) \subseteq H^0(\Omega^1_D)$, where $i : D \to X$ is the inclusion; then the image of $\rho$ contains the image of $\psi_{n-1} : \Lambda^{n-1}V \to H^0(K_D)$. The required inequality now follows from Proposition 4.5, since $V$ has dimension $q$ by the assumption that $a(D)$ generates $\text{Alb}(X)$.

Statement (i) of Proposition 4.6 has been proven in the case of surfaces fibered over $\mathbb{P}^1$ by Xiao Gang [Xi]. The following corollary generalizes to arbitrary dimension the main result of [Xi].

Corollary 4.7. Let $X$ be a smooth projective variety with albdim $X = \dim X = n$ and let $D > 0$ be an irreducible divisor of $X$. If $h^0(D) = r + 1 \geq 2$, then

$$h^0(K_D) \geq 2(q + 1 - n) + r.$$
where \( h \in H^0(D) \) is a section defining \( D \). By Proposition 4.6, \( \text{rk} r_D \geq q - n + 1 \) and so applying Lemma 4.1 we obtain \( \text{rk} \text{res}_D \geq q - n + r \). Hence \( h^0(K_D) \geq (q - n + r) + q - n + 2 = 2(q + 1 - n) + r \). \( \square \)

For future reference, we observe the following:

**Corollary 4.8.** Let \( S \) be a smooth complex surface with \( \text{albdim}(S) = 2 \), let \( a: S \to \text{Alb}(S) \) be the Albanese map and let \( C \subseteq S \) be a 1-connected curve having a component \( C_1 \) not contained in the ramification locus of \( a \) and such that \( C_1' > 0 \). Then:

(i) \( h^0(K_S - C) \leq \chi(S) \);
(ii) \( h^0(C|_C) \geq q + C^2 - p_a(C) \).

**Proof.** (i) Note that \( C_1 \) is nef and big; so \( h^1(\mathcal{O}_S(-C_1)) = 0 \), the map \( H^1(\mathcal{O}_S) \to H^1(\mathcal{O}_{C_1}) \) is an injection and \( a(C_1) \) generates \( \text{Alb}(S) \). As by Proposition 4.6 we have \( \text{rk} r_{C_1} \geq q - 1 \), we obtain \( \text{rk} r_C \geq q - 1 \) and so \( h^0(K_S - C) \leq \chi(S) \).

(ii) Since \( C \) is 1-connected, Riemann–Roch on \( C \) gives

\[
\begin{align*}
\text{rk} h^0(C|_C) & = C^2 + h^0(K_S|_C) + 1 - p_a(C) \\
& \geq C^2 + q - p_a(C).
\end{align*}
\]

\( \square \)

### 4.3. The Petri map

Let \( X \) be a smooth projective variety and let \( D \) be an effective divisor on \( X \).

As a tool for studying the rank or \( r_D \) we introduce the **Petri map**, which, in analogy with the case of curves, is the map

\[
\beta_D: H^0(K_X - D) \otimes H^0(D) \to H^0(K_X)
\]

induced by cup product.

The Petri map is strictly related to the infinitesimal structure of Brill–Noether loci, as follows. Let \( r = h^0(D) - 1 \), let \( T \) be the tangent space to \( W^r(D, X) \) at 0 and let \( \alpha: H^1(\mathcal{O}_X) \otimes H^{n-1}(\mathcal{O}_X) \to H^n(\mathcal{O}_X) \) be the map induced by cup product. Then by Proposition 3.3 for all \( \sigma \in T \otimes H^{n-1}(\mathcal{O}_X) \) and \( \psi \in H^0(D) \otimes H^0(K_X - D) \) we have

\[
\alpha(\sigma) \cup \beta_D(\psi) = 0,
\]

and so \( V := \alpha(T \otimes H^{n-1}(\mathcal{O}_X)) \subseteq H^n(\mathcal{O}_X) \) is orthogonal to \( \text{Im} \beta_D \subseteq H^0(K_X) \).

**Proposition 4.9.** Let \( X \) be a smooth projective variety of dimension \( n \) and irregularity \( q \geq n \), let \( D > 0 \) be a divisor of \( X \), let \( r := h^0(D) - 1 \) and let \( T \) be the tangent space to \( W^r(D, X) \) at the point 0. Assume that \( \dim T > 0 \) and that \( X \) has no fibration \( f: X \to Z \) with \( Z \) normal of Albanese general type and \( 0 < \dim Z < n \). Then:

(i) if \( h^0(K_X - D) = 0 \), then \( \text{rk} r_D \geq n(q - n) + 1 \);

(ii) if \( h^0(K_X - D) > 0 \), then

\[
\begin{align*}
\text{rk} r_D \geq \begin{cases} 
(n - 1)(q - n) + \dim T + r & \text{if } \dim T \leq q - n, \\
q(q - n) + 1 + r & \text{if } \dim T \geq q + 1 - n.
\end{cases}
\end{align*}
\]
Proof. (i) If \( h^0(K_X - D) = 0 \) then \( \text{rk}_D = h^0(K_X) \). By Theorem 2.1, under our assumptions the map \( \bigwedge^n H^0(\mathcal{O}_X) \to H^0(K_X) \) does not map any simple tensor to 0, hence Lemma 4.2 gives \( h^0(K_X) \geq n(q - n) + 1 \).

(ii) Let \( \alpha : H^1(\mathcal{O}_X) \otimes H^{n-1}(\mathcal{O}_X) \to H^n(\mathcal{O}_X) \) be the map induced by cup product. As remarked at the beginning of the section, \( V := \alpha(T \otimes H^{n-1}(\mathcal{O}_X)) \subseteq H^n(\mathcal{O}_X) \) is orthogonal to \( \text{Im} \beta_D \subseteq H^0(K_X) \), where \( \beta_D \) is the Petri map. Let \( \mathcal{G}_T \subseteq \mathcal{G}(n, H^1(\mathcal{O}_X)) \) be the subset consisting of the subspaces that have nontrivial intersection with \( T \). Since, as we remarked in (i), the map \( \bigwedge^n H^0(\mathcal{O}_X) \to H^0(K_X) \) does not map any simple tensor to 0, the complex conjugate map \( \bigwedge^n H^1(\mathcal{O}_X) \to H^n(\mathcal{O}_X) \) induces a morphism \( \mathcal{G}_T \to \mathbb{P}(V) \) which is finite onto its image. It follows that \( \dim V \geq \dim \mathcal{G}_T + 1 \). Since, as noticed above, the space \( V \) is orthogonal to \( \text{Im} \beta_D \), the codimension of \( \text{Im} \beta_D \) is \( \geq \dim \mathcal{G}_T + 1 \).

On the other hand, by Lemma 4.1 the dimension of \( \text{Im} \beta_D \) is at least \( h^0(K_X - D) + h^0(D) - 1 \). Since \( h^0(K_X - D) = p_g - \text{rk}_D \) and \( h^0(D) = r + 1 \), one finds that the dimension of \( \text{Im} \beta_D \) is \( \leq \text{rk}_D - r \). So \( \text{rk}_D \geq \dim \mathcal{G}_T + r + 1 \), which is precisely the statement. \( \square \)

Arguing as in the proof of Corollary 4.7, one obtains the following:

**Corollary 4.10.** Let \( X \) be a smooth projective variety of dimension \( n \) and irregularity \( q \geq n \) that has no fibration \( f : X \to Z \) with \( Z \) normal of Albanese general type and \( 0 < \dim Z < n \). Let \( D > 0 \) be a divisor of \( X \), let \( r := h^0(D) - 1 \) and let \( T \) be the tangent space to \( \mathbb{W}^r(D, X) \) at the point \( 0 \). Assume that \( r > 0 \) and \( \dim T > 0 \). Then:

(i) if \( h^0(K_X - D) = 0 \), then \( h^0(K_D) \geq (n + 1)(q - n) + r + 2 \);
(ii) if \( h^0(K_X - D) > 0 \), then

\[
h^0(K_D) \geq \begin{cases} n(q - n) + \dim T + 2r + 1 & \text{if } \dim T \leq q - n, \\ (n + 1)(q - n) + 2r + 2 & \text{if } \dim T \geq q + 1 - n. \end{cases}
\]

5. Brill–Noether theory for singular curves

Here we prove a generalization of the classical results on the Brill–Noether loci of smooth curves to the case of a compact subgroup of the Jacobian of a reduced connected curve. The results of this section are used in Section 6 to prove the analogous result for smooth irregular surfaces (Thm. 6.2).

Assume that \( C \) is a reduced connected projective curve with irreducible components \( C_1, \ldots, C_s \); for every \( i \), denote by \( \nu_i : C_i^\nu \to C_i \) the normalization map. We refer the reader to [BLR, §9.2, 9.3] for a detailed description of the Jacobian \( \text{Pic}^0(C) \). We just recall here that \( \text{Pic}^0(C) \) is a smooth algebraic group and that there is an exact sequence

\[
0 \to G \to \text{Pic}^0(C) \xrightarrow{f} \text{Pic}^0(C_1^\nu) \times \cdots \times \text{Pic}^0(C_s^\nu) \to 0,
\]

where \( G \) is a smooth connected linear algebraic group and \( f(\eta) = (\nu_1^\nu \eta, \ldots, \nu_s^\nu \eta) \). Notice that if \( T \subseteq \text{Pic}^0(C) \) is a complete subgroup, then \( G \cap T \) is a finite group, and therefore the induced map \( T \to \text{Pic}^0(C_1^\nu) \times \cdots \times \text{Pic}^0(C_s^\nu) \) has finite kernel.
Fix \( L \in \text{Pic}(C) \), an integer \( r \geq 0 \) and a complete connected subgroup \( T \subseteq \text{Pic}^0(C) \), and consider the Brill–Noether locus \( W^n_t(L, C) := \{ \eta \in T \mid h^0(L \otimes \eta) \geq r + 1 \} \).

As in the case of a smooth curve \( C \), we define the Brill–Noether number \( \rho(t, r, d) := t - (r + 1)(p_a(C) - d + r) \), where \( d \) is the total degree of \( L \) and \( t = \dim T \). In complete analogy with the classical situation, we prove:

**Theorem 5.1.** Let \( r \geq 0 \) be an integer, let \( C \) be a reduced connected projective curve and let \( L \) be a line bundle on \( C \) of total degree \( d \). If \( T \subseteq \text{Pic}^0(C) \) is a complete connected subgroup of dimension \( t \) such that for every component \( C_i \) of \( C \) the map \( T \to \text{Pic}^0(C^i) \) has finite kernel, then:

(i) if \( \rho(t, r, d) \geq 0 \), then \( W^n_t(L, C) \) is nonempty;
(ii) if \( \rho(t, r, d) > 0 \), then \( W^n_t(L, C) \) is connected, it generates \( T \) and each of its components has dimension \( \geq \min\{\rho(t, r, d), t\} \).

**Proof.** The proof follows closely the proof given by Fulton and Lazarsfeld in the case of a smooth curve (cf. [FL], [La, §6.3.B, 7.2]).

Denote by \( \mathcal{P} \) the restriction to \( C \times T \) of a normalized Poincaré line bundle on the product \( C \times \text{Pic}^0(C) \). Let \( H \) be a sufficiently high multiple of an ample line bundle on \( C \) and let \( M := L \otimes H \). Recall that for any product of varieties we denote by \( \text{pr}_i \) the projection onto the \( i \)-th factor; we define

\[
E := \text{pr}_2^*(\text{pr}_1^* M \otimes \mathcal{P}).
\]

By the choice of \( H \), \( E \) is a vector bundle of rank \( d + \deg H + 1 - p_a(C) \) on \( T \) and for every \( \eta \in T \) the natural map \( E \otimes C(\eta) \to H^0(M \otimes \eta) \) is an isomorphism and \( M \otimes \eta \) is generated by global sections.

We let \( Z = x_1 + \cdots + x_m \in |H| \) be a general divisor and we define \( F := \text{pr}_2^*(\text{pr}_1^* M|_Z \otimes \mathcal{P}) \). The sheaf \( F \) is a vector bundle of rank \( m = \deg H \) on \( \text{Pic}^0(C) \) and the evaluation map \( \text{pr}_1^* M \otimes \mathcal{P} \to \text{pr}_1^* M|_Z \otimes \mathcal{P} \) induces a sheaf map \( E \to F \). The locus where this map drops rank by \( r + 1 \) is \( W^n_t(L, C) \).

By Theorem II and Remark 1.9 of [FL], to prove the theorem it suffices to show that \( \text{Hom}(E, F) \) is an ample vector bundle. We have \( F = \bigoplus_i \mathcal{P}_{x_i} \), where \( \mathcal{P}_{x_i} \) is (isomorphic to) the restriction of \( \mathcal{P} \) to \( \{ x_i \} \times T \). Since \( \mathcal{P} \) is the restriction of a normalized Poincaré line bundle, \( \mathcal{P}_{x_i} \) is algebraically equivalent to \( \mathcal{O}_T \). Hence \( \text{Hom}(E, F) = \bigoplus_{i=1}^n (E^\vee \otimes \mathcal{P}_{x_i}) \) is ample if and only if \( E^\vee \) is ample.

To show the ampleness of \( E^\vee \) we adapt the proof of [La, Thm. 6.3.48]. Denote by \( \xi \) the linear equivalence class of the tautological line bundle on \( \mathbb{P}(E^\vee) \); we are going to show that for any irreducible positive-dimensional subvariety \( V \) of \( \mathbb{P}(E^\vee) \) the cycle \( V \cap \xi \) is represented, up to numerical equivalence, by a proper nonempty subvariety of \( V \).

Given a point \( x \in C \), the evaluation map \( E \to \mathcal{P}_{x} \) is surjective, since \( M \otimes \eta \) is globally generated for every \( \eta \in T \), hence it defines an effective divisor \( I_x \) algebraically equivalent to \( \xi \). Denote by \( p : \mathbb{P}(E^\vee) \to T \) the natural projection. A point \( v \in \mathbb{P}(E^\vee) \) is determined by a section \( s_v \in H^0(M \otimes p(v)) \), and \( v \in I_x \) if and only if \( s_v(x) = 0 \). Let \( C_i \) be a component of \( C \) such that the general element of \( V \) does not vanish identically on \( C_i \). If the support of the zero locus of \( s_v \) on \( C_i \) varies, then for a general \( x \in C_i \) the set \( V \cap I_x \)
is a proper nonempty subvariety algebraically equivalent to $V \cap \xi$ and we are done. So assume that for general $v \in V$ the support of the zero locus of $v$ on $C_i$ is constant; then, pulling back via $\nu_i: C_i^\nu \to C_i$, we see that the line bundle $\nu_i^*(M \otimes p(v))$ stays constant as $v \in V$ varies. Since the map $T \to \text{Pic}^0(C_i^\nu)$ has finite kernel by assumption, $p(V)$ is a point $\eta_V \in T$ and $V \subseteq \mathbb{P}(H^0(M \otimes \eta_V))$. Since $\dim V > 0$ and $\xi$ restricts to the class of a hyperplane of $\mathbb{P}(H^0(M \otimes \eta_V))$, the cycle $V \cap \xi$ is represented by a proper nonempty subvariety of $V$ also in this case. This completes the proof. \qed

**Remark 5.2.** The proof of Theorem 5.1 does not extend to the case of a complete subgroup $T \subseteq \text{Pic}^0(C)$ such that the map $T \to \text{Pic}^0(C)$ does not have finite kernel for some component $C_i$ of $C$. Indeed, take $C = C_1 \cup C_2$, with $C_i$ smooth curves of genus $g_i > 0$ meeting transversely at only one point $P$, and $T = \text{Pic}^0(C_1) \subseteq \text{Pic}^0(C) = \text{Pic}^0(C_1) \times \text{Pic}^0(C_2)$. Twisting by $H \otimes \eta, \eta \in T$, the exact sequence $0 \to \mathcal{O}_{C_2}(-P) \to \mathcal{O}_C \to \mathcal{O}_{C_1} \to 0$ and taking global sections, one gets inclusions

$$H^0(\mathcal{O}_{C_2}(H - P)) = H^0(\mathcal{O}_{C_2}(H - P) \otimes \eta) \hookrightarrow H^0(\mathcal{O}_C(H) \otimes \eta)$$

that sheafify to a vector bundle map $\mathcal{O}_T \otimes H^0(\mathcal{O}_{C_2}(H - P)) \to E$. So the bundle $E^\nu$ is not ample.

We do not know whether the statement of Theorem 5.1 still holds without this assumption on $T$.

### 6. Brill–Noether theory for curves on irregular surfaces

Our approach to the study of the Brill–Noether loci $W^r(D, X)$ for an effective divisor $D$ in an $n$-dimensional variety $X$ of maximal Albanese dimension consists in comparing it with a suitable Brill–Noether locus on the $(n - 1)$-dimensional variety $D$. Let $i^*: \text{Pic}^0(X) \to \text{Pic}^0(D)$ be the map induced by the inclusion $i: D \to X$ and denote by $T$ the image of $i^*$. The key observation is the following:

**Proposition 6.1.** Let $X$ be a variety of dimension $n > 1$ with $\text{albdim } X = n$ and without irrational pencils of genus $> 1$ and let $D > 0$ be a divisor of $X$. Let $Y$ be a positive-dimensional irreducible component of $W^r_T(D|D, D)$. If $\dim Y \geq 2$ or $0 \in Y$, then $i^{* - 1}Y$ is a component of $W^r(D, X)$.

**Proof.** Let $V^1(X) = \{\eta \in \text{Pic}^0(X) \mid h^1(\eta) > 0\}$ be the first Green–Lazarsfeld locus (see §2.2).

Denote by $U$ the complement of $V^1(X)$ in $\text{Pic}^0(X)$; for $\eta \in U$, the short exact sequence

$$0 \to \eta \to \mathcal{O}_X(D + \eta) \to (D + \eta)|_D \to 0$$

induces an isomorphism $H^0(\mathcal{O}_X(D + \eta)) \cong H^0((D + \eta)|_D)$. Hence $U \cap W^r(D, X) = U \cap i^{* - 1}W^r_T(D|D, D)$ and to prove the claim it is enough to show that $i^{* - 1}Y \nsubseteq V^1(X)$. By Theorem 2.2, if $\dim Y \geq 2$ this follows from $\dim V^1(X) \leq 1$, and if $0 \in Y$ it follows from the fact that $0$ is an isolated point of $V^1(X)$. \qed
In the case of surfaces, Proposition 6.1 can be made effective. Let \( S \) be a surface with \( q(S) = q \) and let \( C \subset S \) be a curve; we define the Brill–Noether number \( \rho(C, r) := q - (r + 1)p_a(C) - C^2 + (C - K_S C)/2 \). Recalling that by the adjunction formula \( q + C^2 - p_a(C) = q - 1 + (C^2 - K_S C)/2 \).

**Theorem 6.2.** Let \( r \geq 0 \) be an integer. Let \( S \) be a surface with irregularity \( q > 1 \) that has no irrational pencil of genus \( q \) > 1 and let \( C \subset S \) be a reduced curve such that \( C^2 \) > 0 for every irreducible component \( C_i \) of \( C \).

(i) If \( \rho(C, r) > 1 \) or \( \rho(C, r) = 1 \) and \( V^1(S) = \{ \eta \in \text{Pic}^0(S) \mid \ell^1(\eta) > 0 \} \) does not generate \( \text{Pic}^0(S) \), then \( W^r(C, S) \) is nonempty of dimension \( \geq \min( q, \rho(C, r) ) \). 

(ii) If \( \rho(C) > 1 \), or \( \rho(C) = 1 \) and \( C \) is not contained in the ramification locus of the Albanese map, or \( \rho(C) = 1 \) and \( V^1(S) \) does not generate \( \text{Pic}^0(S) \), then \( W(C, S) \) has an irreducible component of dimension \( \geq \min( q, \rho(C) ) \) containing 0.

**Proof.** We start by observing that by the Hodge index theorem any two irreducible components of \( C \) intersect, hence in particular \( C \) is connected.

Let \( C_i \) be a component of \( C \) and denote by \( C_i^0 \) its normalization; since \( C_i^0 > 0 \), by [CFM, Prop. 1.6] the map \( \text{Pic}^0(S) \rightarrow \text{Pic}^0(C_i) \) is an injection. Since \( \text{Pic}^0(S) \) is projective and the kernel of \( \text{Pic}^0(C_i) \rightarrow \text{Pic}^0(C_i^0) \) is an affine algebraic group, it follows that the map \( \text{Pic}^0(S) \rightarrow \text{Pic}^0(C_i^0) \) has finite kernel and we may apply Theorem 5.1.

By Theorem 5.1, if \( \rho(C, r) > 0 \) then \( W^r_{\text{Pic}^0(S)}(C, C) \) is nonempty, it generates \( \text{Pic}^0(S) \) and all its components have dimension \( \geq \min( q, \rho(C, r) ) \). Claim (i) follows directly from Proposition 6.1 if \( \rho(C, r) > 1 \). If \( \rho(C, r) = 1 \) and \( V^1(S) \) does not generate \( \text{Pic}^0(S) \), then there exists a positive-dimensional component \( Y \) of \( W^r_{\text{Pic}^0(S)}(C, C) \) not contained in \( V^1(S) \) and arguing as in the proof of Proposition 6.1 one shows that \( Y \) is a component of \( W^r(C, S) \).

By Proposition 6.1 to prove claim (ii) it is enough to show that \( 0 \in W^r_{\text{Pic}^0(S)}(C, C) \), that is, \( \ell^0(C) > 0 \).

If \( \rho(C) = 1 \) and \( C \) is not contained in the ramification locus of the Albanese map of \( S \), this follows from Corollary 4.8.

Otherwise assume that \( \rho(C) > 1 \) or \( \rho(C) = 1 \) and \( V^1(S) \) does not generate \( \text{Pic}^0(S) \). Then by claim (i), \( (-1)^r W(C, S) \) has dimension \( \geq \min(q, \rho(C)) \). As previously we conclude that \( (-1)^r W(C, S) \) is not contained in \( V^1(S) \).

Assume for contradiction that \( h^0(C) = 0 \). Then the Riemann–Roch theorem on \( C \) gives \( h^0(K_S | C) = p_a(C) - C^2 - 1 \). Since \( p_a(C) - C^2 - 1 = q - 1 - \rho(C) \), one obtains \( h^0(K_S | C) < q - 1 \) and thus \( h^0(K_S - C) > \chi(S) \).

For every \( \eta \in W(C, S) \) we have \( h^0(K_S + \eta) \geq h^0(K_S + \eta - (C + \eta)) = h^0(K_S - C) > \chi(S) \), hence \( -\eta \in V^1(S) \), a contradiction. This completes the proof.

**Remark 6.3.** There are plenty of irregular surfaces without irrational pencils, for instance complete intersections in abelian varieties and symmetric products of curves (cf. [MP, §2]); indeed such surfaces can be regarded in some sense as “the general case”.
Note that if $S$ has no irrational pencil of genus $> 1$ and $\text{Alb}(S)$ is not isogenous to a product of elliptic curves, then the assumption that $V^1(S)$ does not generate $\text{Pic}^0(S)$ is satisfied, since by Theorem 2.2 the positive-dimensional components of $V^1(S)$ are elliptic curves. In Example 8.5 we describe a surface without irrational pencils of genus $> 1$ such that $V^1(S)$ generates $\text{Pic}^0(S)$.

Furthermore the inequalities of Theorem 6.2 are sharp: see Example 8.1.

7. Applications to curves on surfaces of maximal Albanese dimension

7.1. Curves that do not move in a linear series

Here we apply the results of the previous sections to curves $C$ with $h^0(C) = 1$ on a surface of general type $S$.

The cohomology sequence associated to the restriction sequence for such a curve $C$ gives an exact sequence

$$0 \to H^0(C|C) \to H^1(O_S) \xrightarrow{\cup s} H^1(O_S|C),$$

where $s \in H^0(O_S(C))$ is a nonzero section vanishing on $C$. Hence by Proposition 3.3, the space $H^0(C|C)$ is naturally isomorphic to the tangent space to $W(C, S)$. This remark, together with Proposition 4.9, gives the following:

**Lemma 7.1.** Let $S$ be a surface of general type with irregularity $q > 0$ that has no irrational pencil of genus $> 1$ and let $C \subset S$ be a 1-connected curve with $h^0(C) = 1$. Then one of the following occurs:

(i) $0 \in W(C, S)$ is an isolated point (with reduced structure);
(ii) $0 < h^0(C|C) < q$ and $C^2 + 2q - 4 \leq K_S C$;
(iii) $h^0(C|C) = q$ and $C^2 + 2q - 6 \leq K_S C$.

**Proof.** As we observed above, the tangent space to $W(C, S)$ has dimension equal to $h^0(C|C)$, therefore case (i) occurs for $h^0(C|C) = 0$. If $h^0(C|C) > 0$, then we can apply Proposition 4.9, which gives $h^0(K_S|C) \geq q - 2 + h^0(C|C)$ if $h^0(C|C) < q$, and $h^0(K_S|C) \geq 2q - 3$ if $h^0(C|C) = q$. By Riemann–Roch and by the adjunction formula, we have

$$h^0(K_S|C) = h^0(C|C) + K_S C + 1 - p_a(C) = h^0(C|C) + \frac{K_S C - C^2}{2},$$

and statements (ii) and (iii) follow immediately by plugging this expression in the above inequalities. \qed

**Remark 7.2.** The inequality (ii) of Lemma 7.1 is sharp (cf. Example 8.1). Using the adjunction formula it can be rewritten as

$$C^2 \leq (p_a(C) - q) + 1,$$

or, equivalently, $\rho(C) \leq 1$. 

In the situation of Lemma 7.1(i) we can also find a lower bound for $K_SC$ using the results of Section 6.

**Proposition 7.3.** Let $S$ be a surface of general type with irregularity $q > 1$ that has no irrational pencil of genus $> 1$ and let $C \subset S$ be a curve with $h^0(C) = 1$ and $h^0(C|_C) = 0$. Assume that $C$ is connected and reduced and that every irreducible component $C_i$ of $C$ satisfies $C_i^2 > 0$. Then

$$C^2 + 2q - 4 \leq K_SC,$$

or, equivalently, $C^2 \leq (p_a(C) - q) + 2$.

Furthermore, if equality occurs then $V^1(S)$ generates $\text{Pic}^0(S)$ and $C$ is contained in the ramification locus of the Albanese map.

**Proof.** Since $h^0(C) = 1$ and $h^0(C|_C) = 0$, $0 \in W(C, S)$ is an isolated point. So by Theorem 6.2(ii), $\rho(C) \leq 1$, i.e. $q + C^2 - p_a(C) \leq 1$, and this last inequality can be written as $C^2 + 2q - 4 \leq K_SC$.

The last assertion of the proposition is also an immediate consequence of Theorem 6.2(ii). $\square$

As immediate consequences of the above two propositions we obtain:

**Corollary 7.4.** Let $S$ be a surface of general type with irregularity $q > 1$ that has no irrational pencil of genus $> 1$ and let $C \subset S$ be a curve with $h^0(C) = 1$. Assume that $C$ is connected and reduced and that every irreducible component $C_i \subset C$ satisfies $C_i^2 > 0$. Then

$$C^2 + 2q - 6 \leq K_SC,$$

or, equivalently, $C^2 \leq (p_a(C) - q) + 2$.

Furthermore, if equality holds then $h^0(C|_C) = q$.

**Corollary 7.5.** Let $S$ be a surface of general type with with irregularity $q > 1$ that has no irrational pencil of genus $> 1$ and let $C$ be an irreducible component of the fixed part of $|K_S|$ such that $C^2 > 0$. Then

$$CK_S \geq C^2 + 2q - 4.$$  

**Proof.** We have $h^0(C) = 1$ by assumption and $h^0(C|_C) = 0$ by Corollary 3.5. Hence the required inequality follows from Proposition 7.3. $\square$

In [MPP1] we have characterized surfaces $S$ of irregularity $q > 1$ containing a curve $C$ such that $C^2 > 0$ and $p_a(C) = q$ (i.e., the smallest possible value). By [Xi] (cf. also Corollary 4.7), any irreducible curve with $h^0(C) \geq 2$ must satisfy $p_a(C) \geq 2q - 1$. We know of no example of a curve with $C^2 > 0$ and $q < p_a(C) < 2q - 1$. The next result gives some information on this case:

**Corollary 7.6.** Let $S$ be a surface of general type with irregularity $q \geq 3$ that has no irregular pencil of genus $> 1$ and let $C \subset S$ be an irreducible curve such that $C^2 > 0$ and $p_a(C) \leq 2q - 2$. Then:

(i) $C^2 \leq (p_a(C) - q) + 1$;

(ii) the codimension of the tangent space at 0 to $W(C, S)$ is \( \geq (3q - p_a(C) - 3)/2 \geq (q - 1)/2 \).
Proof. Since by Corollary 4.7 (cf. also [Xi]) we have $h^0(C) = 1$, by Proposition 3.3 the tangent space to $W(C, S)$ at 0 has dimension $w := h^0(C|_C)$. Note that by Lemma 4.1 we have $h^0(K_S|_C) + h^0(C|_C) \leq p_a(C) + 1 < 2q$.

Now observe that $w < q$. In fact, if $w = q$, then, by Proposition 4.9, one has $h^0(K_S|_C) \geq 2q - 3$. Since $p_a(C) \geq h^0(K_S|_C) + h^0(C|_C) - 1$ we obtain $p_a(C) \geq 3q - 4$, contrary to the assumptions $p_a(C) \leq 2q - 2$ and $q \geq 3$. So (i) follows from Corollary 7.4.

Now Clifford’s theorem gives $2w - 2 \leq C^2$. Since $p_a(C) \leq 2q - 2$, from (i) we obtain $w \leq (p_a(C) - q + 3)/2 \leq (q + 1)/2$. Statement (ii) then follows since $w$ is the dimension of the tangent space to $W(C, S)$ at 0.

\[ \square \]

7.2. The fixed part of the paracanonical system

Let $S$ be a smooth surface of general type of irregularity $q \geq 2$ such that $\text{albdim } S = 2$. Recall (cf. [Be2, §3]) that the paracanonical system $\{K_S\}$ of $S$ is the connected component of the Hilbert scheme of $S$ containing a canonical curve. There is a natural morphism $c: \{K_S\} \to \text{Pic}^0(S)$ defined by $[C] \mapsto O_S(C - K_S)$ and the fiber of $c$ over $\eta \in \text{Pic}^0(S)$ is the linear system $|K_S + \eta|$, hence there is precisely one irreducible component $K_{\text{main}}$ of $\{K_S\}$ (the so-called main paracanonical system) that dominates $\text{Pic}^0(S)$. By the generic vanishing theorem of Green and Lazarsfeld, one has $\dim |K_S + \eta| = \chi(S) - 1$ for general $\eta \in \text{Pic}^0(S)$, and so the main paracanonical system $K_{\text{main}}$ has dimension $q + \chi(S) - 1 = p_a(S)$. It is known [Be2, Prop. 4] that if $q$ is even and $S$ has no irrational pencil of genus $> q/2$, then the canonical system $|K_S|$ is an irreducible component of $\{K_S\}$.

The relationship between the fixed part of $K_{\text{main}}$ and the fixed part of $\{K_S\}$ does not seem to have been studied in general. Here we relate the fixed part of $K_{\text{main}}$ to the ramification locus of the Albanese map.

**Proposition 7.7.** Let $S$ be a smooth surface of general type of irregularity $q \geq 2$ that has no irrational pencil of genus $> q/2$ and let $C \subset S$ be an irreducible curve with $C^2 > 0$ that is contained in the fixed part of the main paracanonical system $K_{\text{main}}$. Then $C$ is contained in the ramification locus of the Albanese map of $S$.

**Proof.** By the semicontinuity of the map $\eta \mapsto h^0(K_S - C + \eta)$, $\eta \in \text{Pic}^0(S)$, we have $h^0(K_S - C) \geq \chi(S)$. Assume for contradiction that $C$ is not contained in the ramification divisor of the Albanese map. Then by Corollary 4.8 (i) we have $h^0(K_S - C) = \chi(S)$. By Proposition 3.3 it follows that the bilinear map $H^1(O_S) \otimes H^0(K_S - C) \to H^1(K_S - C)$ given by cup product is zero. Hence for every section $s \in H^0(K_S)$ that vanishes along $C$ and for every $v \in H^1(O_S)$ we have $s \cup v = 0$. Therefore, by the proof of Proposition 3.4, it follows that if $\alpha, \beta \in H^0(\Omega^1_S)$ are such that $\alpha \wedge \beta \neq 0$, then $\alpha \wedge \beta$ does not vanish along $C$.

Consider the Grassmannian $G := G(2, H^0(\Omega^1_S)) \subseteq \mathbb{P}(\bigwedge^2 H^0(\Omega^1_S))$ and the projectivization $T \subset \mathbb{P}(\bigwedge^2 H^0(\Omega^1_S))$ of the kernel of $\bigwedge^2 H^0(\Omega^1_S) \to H^0(K_S)$. By Theorem 2.1 the intersection $T \cap G$ is the union of a finite number of Grassmannians $G(2, V) \subset \mathbb{P}(\bigwedge^2 V)$ where $V \subset H^0(\Omega^1_S)$ is a subspace of the form $p^*H^0(\omega_B)$ for $p: S \to B$ an irrational pencil of genus $> 1$. Since by assumption $S$ has no irrational pencil of genus $> q/2$, if $G_0 \subset G$ is a general codimension $q - 3$ hyperplane section then $G_0 \cap T = \emptyset$.

Brill–Noether loci for divisors on irregular varieties 2051
Hence the image of $G_0$ in $|K_S|$ is a closed subvariety $Z$ of dimension $q - 1$. Hence $(C + |K_S - C|) \cap Z$ is nonempty, that is, there exist $\alpha, \beta \in H^0(\Omega^1_S)$ such that $\alpha \wedge \beta \neq 0$ and $\alpha \wedge \beta$ vanishes on $C$, a contradiction. \hfill $\Box$

8. Examples and open questions

We collect here some examples to illustrate the phenomena that one encounters in studying the Brill–Noether loci of curves on irregular surfaces. We also give an example (Example 8.5) that shows that the hypothesis that $V^1(S)$ does not generate $\text{Pic}^0(S)$ in Theorem 6.2 is not empty, i.e. surfaces $S$ of maximal Albanese dimension without irrational pencils of genus $> 1$ such that $V^1(S)$ generates $\text{Pic}^0(S)$ do exist. We conclude the section by posing some questions.

Example 8.1 (Symmetric products). Let $C$ be a smooth curve of genus $q \geq 3$ and let $X := S^2C$ be the second symmetric product of $C$. The surface $X$ is minimal of general type with irregularity $q$ (cf. [MP, §2.4] for a detailed description of $X$).

For any $P \in C$, the curve $C_P = \{ P + x \mid x \in C \} \subset X$ is a smooth curve isomorphic to $C$, in particular it has genus $q$. It satisfies $C^2_P = 1$, $h^0(C_P) = 1$ and $\rho(C_P) = 1$. If we fix $P_0 \in C$, then it is easy to check that the map $C \to W(C_{P_0}, X)$ defined by $P \mapsto C_P - C_{P_0}$ is an isomorphism, hence Theorem 6.2 is sharp in this case.

Notice also that for every $P \in C$ we have $h^0(K_X|_{C_P}) = q - 1$, hence both Proposition 4.6 and Proposition 4.9 are sharp in this case.

Example 8.2 (Etale double covers of symmetric products). As in Example 8.1, take a smooth curve $C$ of genus $q \geq 3$, let $X := S^2C$ be the second symmetric product and for $P \in C$ let $C_P = \{ P + x \mid x \in C \} \subset X$. Let $f : C' \to C$ be an etale double cover and let $X' := S^2C'$. The involution $\sigma$ of $C'$ associated to the covering $C' \to C$ induces an involution $\tau$ of $X'$ defined by $\tau(A + B) = \sigma(A) + \sigma(B)$. The fixed locus of $\tau$ is the smooth curve $\Gamma = \{ A + \sigma(A) \mid A \in C' \}$, hence $Y := X'/\tau$ is a smooth surface. It is easy to check that $g(Y) = q$ and that $f$ descends to a degree 2 etale cover $Y \to X$.

Denote by $D_P$ the inverse image of $C_P$ in $Y$. The map $D_P \to C_P$ is a connected etale double cover, hence $D_P$ is smooth (isomorphic to $C'$) with $D_P^2 = 2$ and $g(D_P) = 2q - 1$. In this case $\rho(D_P) = 3 - q \leq 0$ although $D_P$ moves in a 1-dimensional algebraic family.

Next we study $h^0(D_P)$. The standard restriction sequence for $D_P$ on $Y$ gives $0 \to H^0(\mathcal{O}_Y) \to H^0(D_P) \to H^0(D_P|_{D_P}) \to H^1(\mathcal{O}_Y)$ and by Proposition 3.3 the last map in the sequence is nonzero for every $P$ since $D_P$ moves algebraically. Hence if $H^0(D_P|_{D_P}) = 1$ (e.g., if $C'$ is not hyperelliptic) then $h^0(D_P) = 1$. Consider now a special case: take $C$ hyperelliptic, $A, B \in C$ two Weierstrass points and $C' \to C$ the double cover given by the 2-torsion element $A - B$, so that the corresponding etale double cover $Y \to X$ is given by the equivalence relation $2(C_A - C_B) \equiv 0$. Then the curves $D_A$ and $D_B$ are linearly equivalent on $Y$ and we have $h^0(D_A) = 2$.

With a little extra work it is possible to show that this is the only instance in which $h^0(D_P) > 1$.

Example 8.3 (The Fano surface of the cubic threefold). This example deals with a well-known 2-dimensional family of curves of genus 11 on a surface of irregularity $q = 5$. 

Let $V = \{ f(x) = 0 \} \subset \mathbb{P}^4$ be a smooth cubic 3-fold. Let $G := G(2, 5)$ be the Grassmannian of lines of $\mathbb{P}^4$. The Fano surface (see [CG] and [Ty]) is the subset $F = F(V) \subset G$ of lines contained in $V$. We recall that $F$ is a smooth surface with irregularity $q = 5$. In fact, let $J(V)$ be the intermediate Jacobian of $V$; the Abel–Jacobi map $F \to J(V)$ induces an isomorphism $\text{Alb}(F) \to J(V)$. Moreover one has $H^2(F, \mathbb{C}) \cong \bigwedge^2 H^1(F, \mathbb{C}), K_F^2 = 45, \chi(O_F) = 6, p_g(F) = 10$ and $c_2(F) = 27$.

Following Fano, for any $r \in F$ we consider the curve
\[ C_r = \{ s \in F : s \cap r \neq \emptyset \}. \]
We have $h^0(C_r) = 1, C_r^2 = 5, p_g(C_r) = 11$ and $K_F \sim_{\text{alg}} 3C_r$; in addition, the general $C = C_r$ is smooth (see [CG] and [Ty]).

We remark that $W(C, F)$ contains a 2-dimensional variety isomorphic to $F$, while one would expect it to be empty, since $\rho(C) = -1$. On the other hand, since the family has dimension 2, we have $h^0(O_C(C)) = 2$, hence $W^2_2(C) \neq \emptyset$ and $C$ is not Brill–Noether general. In fact the corresponding Brill–Noether number is $\rho(11, 5, 1) = 11 - 2(11 - 5 + 1) = -3$. Moreover there is a degree 2 étale map $C \to D$, where $D$ is a smooth plane quintic, and $\text{Alb}(F)$ is isomorphic to the Prym variety $P(C, D)$ of the covering, thus the curve $C$ has very special moduli.

Nevertheless we will see that the family $\{ C_r \}_{r \in F}$ has a good infinitesimal behaviour. Firstly we recall that $h^0(K_F - C_r) = 3$ by [Ty, Cor. 2.2]. Let $T$ be the tangent space to $W(C_r, F)$ at $0$; since $\dim T \geq 2$, the image $V \subset H^2(O_F) \cong \bigwedge^2 H^1(O_F)$ of $T \otimes H^1(O_F)$ has dimension $\geq 7$. On the other hand, $V$ is orthogonal to the image in $H^0(K_S)$ of the Petri map $\beta_C : H^0(C) \otimes H^0(K_F - C_r) \to H^0(K_F)$, therefore $\dim V \leq p_g(F) - h^0(K_F - C_r) = 7$. So we have $\dim V = 7, \dim T = 2$ and in this case the dimension of the family is predicted by the Petri map.

Example 8.4 (Ramified double covers). Let $X$ be a smooth surface of irregularity $q$ such that the Albanese map $X \to \text{Alb}(X)$ is an embedding (for instance, take for $X$ a complete intersection in an abelian variety), and let $\pi : S \to X$ be the double cover given by a relation $2L \equiv B$ with $B$ a smooth ample curve. Write $\pi^*B = 2R$; the induced map $\text{Alb}(S) \to \text{Alb}(X)$ is an isomorphism (cf. [MP, §2.4]), hence $R$ is the ramification divisor of the Albanese map of $S$. We have $R \in |\pi^*L|$ and, by the projection formula for double covers, for every $\eta \in \text{Pic}^0(S) = \text{Pic}^0(X)$ we have $H^0(R + \eta) = H^0(L + \eta) \otimes H^0(\eta)$, where the first summand is the space of invariant sections and the second one is the space of anti-invariant sections. Hence for $\eta \neq 0$ all sections are invariant, while for $\eta = 0$ the curve $R$ is the zero locus of the only (up to scalars) anti-invariant section. Hence $R$ moves only linearly on $S$, as predicted by Proposition 3.4.

This construction can also be used to produce examples of surfaces of fixed irregularity $q$ that contain smooth curves $C$ with $C^2 > 0, h^0(C) = 1$ and unbounded genus. Assume that $X$ contains a smooth curve $D$ such that $D^2 > 0$ and $h^0(D) = 1$ (for instance, take as $X$ a symmetric product as in Example 8.1). Set $C := \pi^{-1}(D)$; if $B$ meets $D$ transversely, then $C$ is smooth of genus $2g(D) - 1 + LD$, hence $g(C)$ can be arbitrarily large. Again by the projection formulae, for every $\eta \in \text{Pic}^0(S) = \text{Pic}^0(X)$ we have $h^0(C + \eta) = h^0(D + \eta) + h^0(D + \eta - L)$. Hence if $L - D > 0$, we have $h^0(C + \eta) = h^0(D + \eta) = 1$ and $W(C, S) = W(D, X)$.
Example 8.5. An example of a surface $S$ without pencils of genus $> 1$ such that $V^1(S)$ generates $\text{Pic}^0(S)$ can be constructed as follows.

Let $E$ be an elliptic curve, let $C \to E$ and $E' \to E$ be double covers with $C$ a curve of genus 2 and $E'$ an elliptic curve, and set $B := C \times_E E'$. The map $B \to E$ is a $\mathbb{Z}_2^2$-cover and $B$ has genus 3. We denote by $\alpha$ the element of the Galois group of $B \to E$ such that $B/(\alpha) = E'$, and by $\beta, \gamma$ the remaining nonzero elements. The curves $B/(\beta)$ and $B/(\gamma)$ have genus 2.

Now choose elliptic curves $E_1$, $E_2$, $E_3$ and for $i = 1, 2, 3$ let $B_i \to E_i$ and $\alpha_i, \beta_i, \gamma_i$ be as above. Let $X := B_1 \times B_2 \times B_3$ and let $G$ be the subgroup of $\text{Aut}(X)$ generated by $g_1 = (\alpha_1, \beta_2, \gamma_3)$ and $g_2 = (\beta_1, \gamma_2, \alpha_3)$; note that $G$ acts freely on $X$. Let $S' \subset X$ be a smooth ample divisor which is invariant under the $G$-action and let $S := S'/G$; we denote by $f_i: S \to E_i$ the induced map, $i = 1, 2, 3$. The surfaces $S'$ and $S$ are minimal of general type. By the Lefschetz Theorem, $\text{Alb}(S') = \text{Alb}(X) = J(B_1) \times J(B_2) \times J(B_3)$. It is immediate to check that $q(S) = 3$ and that the map $S \to A = E_1 \times E_2 \times E_3$ induces an isogeny $\text{Alb}(S) \to A$. Consider the étale cover $S_1 = S'/(g_1) \to S$; the map $S' \to B_1$ induces a map $S_1 \to E'_1 = B_1/(\alpha_1)$ which is equivariant for the action of $G/(g_1)$. The group $G/(g_1)$ acts freely on $E'_1$, hence the cover $S_1 \to S$ is obtained from $E'_1 \to E_1$ by base change. It follows that the 2-torsion element $\eta_1 \in \text{Pic}(S)$ associated to this double cover is a pull back from $E_1$. Thus $\eta_1$ belongs to $\text{Pic}^0(S)$.

The map $S' \to B_2$ induces a fibration $S_1 \to C_2 = B_2/(\beta_2)$. There is a commutative diagram

$$
\begin{array}{ccc}
S_1 & \longrightarrow & S \\
\downarrow & & \downarrow f_2 \\
C_2 & \longrightarrow & E_2
\end{array}
$$

where the map $S_1 \to S$ is obtained from $C_2 \to E_2$ by base change and normalization. This means that the fibration $S_1 \to C_2$ has two double fibres $2F_1$ and $2F_2$, occurring at the ramification points of $f_2$, and that $\eta_1 = F_1 - F_2 + \alpha$ for some $\alpha \in \text{Pic}^0(E_2)$, hence $\eta_1$ restricts to 0 on the general fiber of $f_2$. By [Be4, Thm. 2.2], this implies that $\eta_1 + f_2^* \text{Pic}^0(E_2)$ is a component of $V^1(S)$. A similar argument shows that $V^1(S)$ contains translates of $f_1^* \text{Pic}^0(E_1)$ and $f_2^* \text{Pic}^0(E_2)$. Since $\text{Alb}(S)$ is isogenous to $E_1 \times E_2 \times E_3$, it follows that $V^1(S)$ generates $\text{Pic}^0(S)$.

To conclude, we show that if the curves $E_i$ are general, then $S$ has no irrational pencil of genus $> 1$. In this case $\text{Hom}(E_i, E_j) = 0$ if $i \neq j$, hence $\text{End}(A) = \mathbb{Z}^3$. Assume for contradiction that $S \to B$ is an irrational pencil of genus $b > 1$. Since the map $S \to A$ is generically finite by construction and $q(S) = 3, b = 2$ is the only possibility. Then we have a map with finite kernel $J(B) \to A$. Let $W$ be the image of $J(B)$ in $A$. Consider the endomorphism $\phi$ of $A$ defined as $A \to A/W = (A/W)^\vee \to A^\vee = A$ (both $A$ and $A/W$ are principally polarized). The connected component of $0 \in \ker \phi$ is $W$, hence $W$ is a product of two of the $E_i$. So the map $S \to W$ has finite fibres, while $S \to J(B)$ is composed with a pencil, and we have a contradiction.

Question 8.6. Let $S$ be a surface of general type of irregularity $q$ and of maximal Albanese dimension. A curve $C \subset S$ with $C^2 > 0$ satisfies $p_a(C) \geq q$ and in [MPP1] we
have proven that if $S$ contains a 1-connected curve $C$ with $C^2 > 0$ and $p_a(C) = q$, then $S$ is birationally a product of curves or the symmetric square of a curve. On the other hand, the curves $D_P$ in Example 8.2 have $D_P^2 > 0$ and genus equal to $2q - 1$. We do not know any surface $S$ containing a curve $C$ with $C^2 > 0$ and arithmetic genus in the intermediate range $q < p_a(C) < 2q - 1$, so it is natural to ask whether such an example exists. Notice that, by Corollary 4.7 (cf. also [Xi]), a curve $C$ with $C^2 > 0$ and $p_a(C) < 2q - 1$ cannot move linearly and that some further restrictions are given in Corollary 7.6. In addition, the image $C'$ of such a curve $C$ via the Albanese map generates $\text{Alb}(C)$ and therefore by the Hurwitz formula $C'$ is birational to $C$. Hence this question is also related to the question of existence of curves of genus $q < p_a(C) < 2q - 1$ that generate an abelian variety of dimension $q$ (see [Pi] for related questions).

**Question 8.7.** On a variety $X$ with albdim $X = \dim X$ there are three intrinsically defined effective divisors:

(a) the fixed part of $|K_X|$;
(b) the ramification divisor $R$ of the Albanese map;
(c) the fixed part of the main paracanonical system $K_{\text{main}}$ (cf. §7.2).

Clearly the fixed part of $|K_X|$ is a subdivisor of $R$. In the case of surfaces, in Proposition 7.7 it is shown that the components $C$ of the fixed part of $K_{\text{main}}$ with $C^2 > 0$ are contained in $R$ if the surface has no irrational pencil of genus $> q/2$.

It would be interesting to know more precisely in arbitrary dimension how these three divisors are related.

**Question 8.8.** In §6 we study the Brill–Noether loci for curves $C$ on a surface $S$, that is, we always assume that $0 \in W(C, S) \neq \emptyset$. It would be very interesting to find numerical conditions on a line bundle $L \in \text{Pic}(X)$, $X$ a smooth projective variety, that ensure that $W(L, X)$ is not empty.

**Acknowledgements.** We wish to thank Angelo Vistoli for many useful mathematical discussions.

1 In our recent preprint [MPP2], we have proven by different methods that for surfaces without irrational pencils of genus $> q/2$ the fixed part of the main paracanonical system is contained in the fixed part of the canonical system.

Brill–Noether loci for divisors on irregular varieties 2057
