Resonances and lower resolvent bounds

Kiril Datchev, Semyon Dyatlov, and Maciej Zworski

Abstract. We show how the presence of resonances close to the real axis implies exponential lower bounds on the norm of the cut-off resolvent on the real axis.

Mathematics Subject Classification (2010). 35Q40, 35P25.

Keywords. Resolvent estimates, scattering resonances, semiclassical analysis.

1. Introduction

In this note we establish exponential lower bounds on the scattering resolvent on the real line. We show that these lower bounds can be understood in terms of resonances close to the real axis.

To fix the concepts, consider a semiclassical Schrödinger operator on $\mathbb{R}^n$:

$$P(h) = -\hbar^2 \Delta + V(x), \quad x \in \mathbb{R}^n, \quad V \in C_0^\infty(\mathbb{R}^n; \mathbb{R}),$$

(1.1)

$$\text{supp } V \subset B(0, R_0); \quad V(0) = V_0 > 0, \quad V'(0) = 0, \quad V''(0) > 0;$$

(1.2a)

$$x \cdot V'(x) \leq 0 \quad \text{on } \{V \leq V_0\}, \quad x \cdot V'(x) < 0 \quad \text{on } \{V = V_0\} \setminus \{0\}.$$  

(1.2b)

Take $R > R_0$ and define the cutoffs

$$\chi = 1_{B(0,R_0)}, \quad \psi = 1_{B(0,R+1) \setminus B(0,R-1)}.$$  

(1.3)

Theorem 3 in §4 shows that for any $R > R_0$ there exists a constant $c > 0$ independent of $h$ and $E_0(h) = V_0 + \mathcal{O}(h)$ such that

$$\|\chi(P(h) - E_0(h) \pm i0)^{-1}\chi\|_{L^2 \to L^2} \geq \exp(c/h),$$

(1.4)

$$\|\psi(P(h) - E_0(h) \pm i0)^{-1}\chi\|_{L^2 \to L^2} \geq \exp(c/h).$$  

(1.5)
A very general exponential upper bound corresponding to (1.4) was first proved by Burq [2], with generalizations by Vodev [19], and more recently by Datchev [4]. The lower bound is immediate from much easier arguments involving quasimodes. The “non-trapping” upper bound (for $R$ large enough)

$$\| \psi (P(h) - E_0(h) \pm i0)^{-1}\psi \|_{L^2 \to L^2} \leq \frac{C_0}{h},$$  \hspace{1cm} (1.6)

was again given by Burq [2] (with a log $1/h$ loss) and Vodev [19] – see [4] for a neat new proof.

It is (1.5) which seems to be the novel aspect. It shows that having a one sided cutoff to the exterior of the interaction region cannot prevent exponential blow up of the resolvent.

The method also applies to the case of Riemannian manifolds, $(M, g)$, considered recently by Rodnianski–Tao [17] – see Fig. 1. In that case the support of $V$ is replaced in (1.3) by the set where the metric is different from the Euclidean metric, and we obtain a sequence of $\lambda_k \to \infty$ such that

$$\| \psi (\Delta_g - \lambda_k \pm i0)^{-1}\chi \|_{L^2(M) \to L^2(M)} \geq e^{c\sqrt{\lambda_k}}.$$  \hspace{1cm} (1.7)

See Theorem 4 in §4 for details.

Figure 1. Examples of manifolds for which the estimate (1.7) holds: on the left a surface of revolution with two Euclidean ends to which Theorem 4 applies directly; on the right a surface with one end to which a modification of the same method applies (see [7]). The same examples work in any dimension.
The reason behind these estimates is the presence of resonances close to real axis. The resolvent
\[ R_h(z) = (P(h) - z)^{-1} : L^2(\mathbb{R}^n) \to H^2(\mathbb{R}^n), \quad z \not\in [0, +\infty), \]
has a meromorphic continuation to the Riemann surface of \( \sqrt{z} \) for \( n \) odd, and to the Riemann surface of \( \log z \) for \( n \) even, as a family of operators
\[ L^2_{\text{comp}}(\mathbb{R}^n) \to H^2_{\text{loc}}(\mathbb{R}^n), \]
see for example \([6],[13]\), and references given there. Resonances, defined as the poles of this continuation, replace discrete spectral data for problems on non-compact domains. For the situations considered here, in particular for the case (1.1), Rellich’s theorem (see \([6]\)) shows that there are no resonances on the positive real axis, that is, the operators \( (P(h) - E \pm i0)^{-1} \) are well-defined for \( E > 0 \).

Theorem 2 in \S3 gives general lower bounds based on existence of resonances with certain properties. It is then applied in Theorems 3 and 4 in \S4 to obtain examples, in particular of Riemannian manifolds with Euclidean ends.

The simple proofs here are based on previous work on scattering resonances, in particular those by Bony and Michel \([1]\), Gérard and Martinez \([8]\), Helffer and Sjöstrand \([10]\), Tang and Zworski \([18]\) and Nakamura, Stefanov, and Zworski \([15]\). To make the basic idea accessible, we present in \S2 an elementary and self-contained one dimensional example which captures the basic reason for (1.5); the argument of \S2 does not directly use resonances though it could be used to show their existence.

\textbf{Acknowledgements.} We would like to thank André Martinez and András Vasy for helpful discussions of resolvent estimates. We are also grateful for the support by a National Science Foundation postdoctoral fellowship (KD), a Clay Research Fellowship (SD) and by a National Science Foundation grant DMS-1201417 (MZ).

\section{2. An explicit example}

The following one dimensional example shows the reasons for (1.5) in an explicit setting:

\textbf{Theorem 1.} Let \( V \in C^\infty_c(\mathbb{R}) \) be a nonnegative potential satisfying the following conditions (see Figure 2):

\begin{align}
V(x) &= V(-x), \quad V(x) = x^2 + 1 \text{ for } x \in [-1, 1]; \\
V(x) &= 4 - x \text{ for } x \in [2, 3.5]; \quad V(x) < 1 \text{ for } x > 3; \quad \text{supp } V \subset [-5, 5].
\end{align}
Put $R_0 = 4$, fix $R > 5$, and define $\chi, \psi$ by (1.3). Then there exists $c > 0$ and families $E_0(h) = 1 + \mathcal{O}(h)$, $u(h), f(h) \in C^\infty_c(\mathbb{R})$ such that

\begin{align}
(P(h) - E_0(h))u &= f, \quad f = \psi f; \tag{2.2a}
\|\chi u\|_{L^2(\mathbb{R})} &= 1, \quad \|f\|_{L^2(\mathbb{R})} \leq e^{-c/h}. \tag{2.2b}
\end{align}

Note that (2.2) implies (henceforth suppressing the dependence on $h$)

\begin{align}
\|\chi R_h(E_0 \pm i0)\psi\|_{L^2 \to L^2} &\geq e^{c/h}, \tag{2.3}
\|\psi R_h(E_0 \pm i0)\chi\|_{L^2 \to L^2} &\geq e^{c/h}. \tag{2.4}
\end{align}

Indeed, since $u \in C^\infty_c$ and $f = \psi f$, we have $\chi u = \chi R_h(E_0 \pm i0)\psi f$; this shows (2.3). The bound (2.4) follows since $R_h(E_0 \pm i0)^* = R_h(E_0 \mp i0)$.

![Figure 2. The potential $V$ used in Theorem 1.](image)

The key component of the proof of Theorem 1 is the existence of quasimodes for the operator $P - E_0$, namely functions that satisfy $(P - E_0)v = \mathcal{O}(e^{-c/h})$:

**Lemma 2.1.** There exist $h$-dependent families $E_0 = E_0(h) \in \mathbb{R}$, and $v = v(r; h) \in C^\infty([-R, R])$, such that $E_0 = 1 + \mathcal{O}(h)$ and for some $C, c > 0$,

\begin{align}
(P - E_0)v &= 0, \quad \|v\|_{L^2(-3.5, 3.5)} \geq C^{-1}, \quad \|v\|_{H^1_h([-R-1 < |x| < R])} \leq C e^{-c/h}.
\end{align}

Here $H^1_h$ denotes the semiclassical Sobolev space where in the standard definition $D_x$ is replaced by $h D_x$ – see for instance [20, §7.1, §8.3].

To derive Theorem 1 from Lemma 2.1, we take $\chi_0 \in C^\infty_c(-R, R)$ such that $\chi_0 = 1$ on $[-(R-1), R-1]$ and put

\begin{align}
u := \alpha \chi_0 v, \quad f = (P - E_0)u = \alpha [P, \chi_0]v,
\end{align}

here the constant $\alpha = \alpha(h)$ is chosen so that $\|\chi u\|_{L^2} = 1$ and we have $|\alpha| \leq C$. We furthermore see that $\text{supp } f \subset \{R-1 < |x| < R\}$ and $\|f\|_{L^2} \leq e^{-c/h}$ (the constant $C$ can be absorbed into the exponential by replacing $c$ by a smaller constant and taking $h$ small enough).
The rest of this section contains the proof of Lemma 2.1. We take \( \widetilde{R}(h) \geq R \), \( \widetilde{R}(h) = R + O(h) \), to be chosen at the end of this section in (2.15), and let \( v \) be an eigenfunction of \( P \) on \( [\widetilde{R}(h), \widetilde{R}(h)] \) with Dirichlet boundary conditions with eigenvalue \( E_0 \) close to the ground state \( 1 + h \) of the quantum harmonic oscillator \( -\hbar^2 \partial_x^2 + x^2 + 1 \). The existence of such eigenvalue is given by the following

**Lemma 2.2.** For \( h \) small enough and given \( \widetilde{R}(h) \in [R, R+1] \), there exists \( E_0 \in \mathbb{R} \) and \( v \in C^\infty([-\widetilde{R}(h), \widetilde{R}(h)]) \) such that

\[
(P - E_0)v = 0, \quad v(\widetilde{R}(h)) = v(-\widetilde{R}(h)) = 0;
\]

\[
\|v\|_{L^2(-\widetilde{R}(h), \widetilde{R}(h))} = 1, \quad \|v\|_{H^1_h(-\widetilde{R}(h), \widetilde{R}(h))} \leq C, \quad E_0 = 1 + h + O(e^{-1/10h}).
\]

**Proof.** Define

\[
v_1(x) := h^{-1/4}e^{-\frac{x^2}{2h}}, \quad x \in [-1, 1].
\]

Note that, since \( P = -\hbar^2 \partial_x^2 + x^2 + 1 \) on \([-1, 1]\), we have

\[
(P - (1 + h))v_1 = 0, \quad x \in [-1, 1];
\]

\[
\|v_1\|_{L^2(-1/2, 1/2)} \geq C^{-1}, \quad \|v_1\|_{H^1_h((-1/2, 1/2) \subset |x| < 1)} \leq Ce^{-\frac{1}{10h}}.
\]

Now, take \( \overline{\chi} \in C^\infty_c(-1, 1) \) such that \( \overline{\chi} = 1 \) on \([-1/2, 1/2]\). Then

\[
\|\overline{\chi}v_1\|_{L^2} \geq C^{-1}, \quad \|(P - (1 + h))\overline{\chi}v_1\|_{L^2} \leq Ce^{-\frac{1}{10h}},
\]

and \( \overline{\chi}v_1 \) satisfies the Dirichlet boundary conditions at \( \pm \widetilde{R}(h) \) (since it vanishes there). Now, \( P - (1 + h) \) is self-adjoint on \( L^2([-\widetilde{R}(h), \widetilde{R}(h)]) \) when Dirichlet boundary conditions are imposed. Since the norm of its inverse is at least \( C^{-1}e^{\frac{h}{100}} \), we see that this operator has an eigenvalue which is \( O(e^{-\frac{1}{10h}}) \); we denote the corresponding eigenvalue of \( P \) by \( E_0 \) and the corresponding \( L^2 \) normalized eigenfunction by \( v \). Finally, to establish a bound on the \( H^1_h \) norm of \( v \) it suffices to multiply the equation \( (P - E_0)v = 0 \) by \( \overline{\chi} \) and integrate by parts.

Lemma 2.1 follows once we establish the following exponential bound on \( v \):

\[
\|v\|_{H^1_h((3.5 \leq |x| \leq \widetilde{R}(h)))} \leq Ce^{-c/h}.
\]

We will show (2.5) for positive \( x \); the case of negative \( x \) is handled similarly (since \( V \) is even, \( v \) can be taken to be even as well). The main idea is the following: if \( v \) is not exponentially large in \( 1/h \) near, say, \( x = 2 \) relative to its size on \([3.5, \widetilde{R}(h)]\), then one expects \( v \) to give an approximate Dirichlet eigenfunction to the operator \( P \) on \([2, \widetilde{R}(h)]\) with eigenvalue \( E_0 \). However, then \( E_0 \) has to satisfy a quantization

Resonances and lower resolvent bounds

603
condition determined by the behavior of $V$ on $[2, \tilde{R}(h)]$; since $E_0 = 1 + h + o(h)$, one can choose $\tilde{R}(h)$ to ensure that the quantization condition is not satisfied and thus obtain a contradiction.

For $f_1, f_2 \in C^\infty(\mathbb{R})$ we define the (semiclassical) Wronskian by

$$W(f_1, f_2) = f_1 \cdot h \partial_x f_2 - f_2 \cdot h \partial_x f_1,$$

and note that

$$h \partial_x W(f_1, f_2) = f_2 \cdot (P - E_0) f_1 - f_1 \cdot (P - E_0) f_2.$$

The interval $[2, R]$ can be split into three regions where the behavior of $v$ is different, based on the sign of $V(x) - 1$: the “elliptic” or classically forbidden region $[2, 3]$, where $v$ will grow exponentially in $h$ as $x$ decreases, the neighborhood of the turning point $x = 3$, and the “hyperbolic” region $(3, R)$, where the equation $(P(h) - E_0)v = 0$ has two solutions which are bounded as $h \to 0$.

We start with the hyperbolic region, considering the phase function

$$\Phi(x) := \int_{4 - E_0}^x \sqrt{E_0 - V(y)} \, dy.$$

Note that $\Phi$ is well-defined on $x \in [4 - E_0, R + 1]$, since

$$\sqrt{E_0 - V(y)} = \sqrt{y - (4 - E_0)} \quad \text{for} \quad y \in [4 - E_0, 3.5];$$

in fact, we have

$$\Phi(x) = \frac{2}{3}(x - (4 - E_0))^{3/2} \quad \text{for} \quad x \in [4 - E_0, 3.5]. \quad (2.6)$$

Define now the following WKB solutions:

$$v_\pm(x) := (E_0 - V(x))^{-1/4} e^{\pm \frac{i \Phi(x)}{h}}, \quad x \in [3.5, R + 1],$$

then we have uniformly in $x \in [3.5, R + 1]$,

$$(P - E_0)v_\pm(x) = o(h^2), \quad W(v_+, v_-)(x) = -2i + o(h). \quad (2.7)$$

Denote

$$v(x) = (v_1(x), v_2(x)) := (W(v, v_+)(x), W(v, v_-)(x)),$$

then

$$v(x) = \frac{v_2(x) \cdot v_+(x) - v_1(x) \cdot v_-(x)}{W(v_+, v_-)(x)}, \quad (2.8)$$

$$h \partial_x v(x) = \frac{v_2(x) \cdot h \partial_x v_+(x) - v_1(x) \cdot h \partial_x v_-(x)}{W(v_+, v_-)(x)}. \quad (2.9)$$
Since \((P - E_0)v = 0\), we have
\[
h\partial_x W(v, v_\pm) = -v \cdot (P - E_0)v_\pm.
\]

From (2.7) and (2.8) we see that for \(x \in [3.5, R + 1]\),
\[
|\partial_x v(x)| \leq C h|v(x)|.
\]
Therefore,
\[
v(x) = v(3.5)(1 + \mathcal{O}(h)), \quad x \in [3.5, \tilde{R}(h)]. \tag{2.10}
\]
This and (2.8), (2.9) show that
\[
\|v\|_{H^1(3.5, \tilde{R}(h))} \leq C |v(3.5)|. \tag{2.11}
\]

The final component of the proof is the following solution in the region \([2, 3.5]\) which describes the transformation from the hyperbolic to the elliptic region via the turning point, and is exponentially decaying in the elliptic region. Since \(V(x) = 4 - x\) in this region, the solution is given by an Airy function, and its properties are as follows:

**Lemma 2.3.** There exists a solution \(w(x)\) to the equation \((P - E_0)w = 0\) for \(x \in [2, 3.5]\) such that \(\|w\|_{H^1(2.2, 5)} \leq Ce^{-c/h}\) for some constants \(C, c > 0\) and
\[
\left( \begin{array}{c}
w(x) \\
h\partial_x w(x)
\end{array} \right) = e^{i\pi/4} \left( \begin{array}{c}
v_+(x) \\
h\partial_x v_+(x)
\end{array} \right) - e^{-i\pi/4} \left( \begin{array}{c}
v_-(x) \\
h\partial_x v_-(x)
\end{array} \right) + \mathcal{O}(h), \quad x \in [3.25, 3.5]. \tag{2.12}
\]

**Proof.** The solution \(w\) is given by
\[
w(x) = 2i\sqrt{\pi}h^{-1/6} \text{Ai}(h^{-2/3}(4 - E_0 - x)),
\]
and its properties follow from the following asymptotic formulae for the Airy function \(\text{Ai}\) as \(y \to +\infty\):
\[
\text{Ai}(y) = \frac{y^{-1/4}}{2\sqrt{\pi}} \exp\left(- \frac{2}{3}y^{3/2}\right)(1 + \mathcal{O}(y^{-3/2})),
\]
\[
\text{Ai}(-y) = \frac{y^{-1/4}}{\sqrt{\pi}} \left( \sin \left( \frac{2}{3}y^{3/2} + \frac{\pi}{4} \right) + \mathcal{O}(y^{-3/2}) \right),
\]
and similar formulæ for its derivatives, see for example [11, (7.6.20), (7.6.21)].
We are now ready to finish the proof of (2.5). Since
\[(P - E_0)v = (P - E_0)w = 0\] on \([2, 3.5]\),
the Wronskian \(W(v, w)\) is constant on this interval. Using the estimates
\[\|v\|_{H^1_h(2,2.5)} \leq C, \quad \|w\|_{H^1_h(2,2.5)} \leq Ce^{-c/h},\]
we see that
\[|W(v, w)| \leq Ce^{-c/h}.\]

Now, computing the same Wronskian at \(x = 3.5\) and using (2.12), we get
\[W(v, w) = e^{i\pi/4}v_1(3.5) - e^{-i\pi/4}v_2(3.5) + O(h)|v(3.5)|.\]

It remains to prove that, for a certain choice of \(\tilde{R}(h)\) independent of \(E_0\), we have
\[|e^{i\pi/4}v_1(3.5) - e^{-i\pi/4}v_2(3.5)| \geq C^{-1}|v(3.5)|. \quad (2.13)\]
Indeed, in this case \(|v(3.5)| \leq Ce^{-c/h}\), which together with (2.11) gives (2.5).

Using (2.10), we rewrite (2.13) as follows:
\[|e^{i\pi/4}v_1(\tilde{R}(h)) - e^{-i\pi/4}v_2(\tilde{R}(h))| \geq C^{-1}|v(\tilde{R}(h))|. \quad (2.14)\]
Since \(v\) satisfies the Dirichlet boundary condition at \(\tilde{R}(h)\), we have
\[W(v, v_\pm)(\tilde{R}(h)) = -E_0^{-1/4}e^{\pm i \Phi(\tilde{R}(h))/h} \cdot h \partial_x v(\tilde{R}(h)),\]
so that \(|v_1(\tilde{R}(h))|, |v_2(\tilde{R}(h))| \geq C^{-1}|v(\tilde{R}(h))|\) and
\[e^{-i\pi/4}v_2(\tilde{R}(h)) = \exp \left( -\frac{i}{h} \left( 2\Phi(\tilde{R}(h)) + \pi h/2 \right) \right).\]

To prove (2.14), we choose \(\tilde{R}(h) = R + O(h)\), \(\tilde{R}(h) \geq R\), so that
\[\min_{j \in \mathbb{Z}} \left| \Phi(\tilde{R}(h)) + (j + 1/4)\pi h \right| \geq \frac{\pi h}{4}; \quad (2.15)\]
this can be done independently of \(E_0\), since \(E_0 = 1 + h + O(e^{-\frac{1}{\pi h}})\) and thus
\[\Phi(\tilde{R}(h)) = \int_{3-h}^{5} \sqrt{1 + h - V(y)} \, dy + \sqrt{1 + h(\tilde{R}(h) - 5)} + O(e^{-\frac{1}{\pi h}}).\]
3. A general argument

Suppose that $P(h)$ is an operator satisfying the general assumptions of [15], that is a black box self-adjoint operator, close to the Laplacian and having analytic coefficients near infinity and with a barrier at energy $V_0$. (A barrier separates the interaction region from infinity – see (3.3) and Fig. 3.) We assume that $\mathbb{R}^n \setminus B(0, R_0)$ is contained in the “outside” of the black box and the trapped set at energy $V_0$. We also assume the Hilbert space on which the operator acts, $\mathcal{H} = \mathcal{H}_{R_0} \oplus L^2(\mathbb{R}^n \setminus B(0, R_0))$, is equipped with an involution $u \mapsto \bar{u}$ equal to complex conjugation on $L^2(\mathbb{R}^n \setminus B(0, R_0))$ and satisfying $\overline{zu} = \bar{z}u, z \in \mathbb{C}$. The abstract reality assumption on $P(h)$ reads $P(h)u = P(h)\bar{u}$.

An example to keep in mind is given by the operator

$$P(h) = -h^2 \Delta_g + V : H^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n),$$

where the measure on $L^2$ is obtained from the Riemannian metric and

$$\mathcal{H} := L^2(\mathbb{R}^n).$$

The potential $V(x)$ and the metric coefficients $g^{ij}(x)$ are smooth, extend analytically to $\Omega := \{z \in \mathbb{C}^n : |z| \geq R_1, \ |\text{Im} \ z| \leq \delta|z|\}$, and

$$g^{ij}(z) - \delta^{ij} \to 0, \quad V(z) \to 0, \quad |z| \to \infty, \ z \in \Omega.$$  \hspace{1cm} (3.1)

The trapped set, $K_E$, at energy $E > 0$ is then defined by

$$K_E := \{(x, \xi) \in \mathbb{R}^n \times \mathbb{R}^n : p(x, \xi) = E, \ e^{tH_p(x, \xi)} \not\to \infty, \ t \to \pm \infty\},$$  \hspace{1cm} (3.2)

where

$$H_p := \sum_{j=1}^n \partial_{\xi_j} p \cdot \partial_{x_j} - \partial_{x_j} p \cdot \partial_{\xi_j},$$

$$p(x, \xi) := \sum_{i, j=1}^n g^{ij}(x)\bar{\xi}_j \xi_i + V(x).$$

The assumption on the interaction region in this case means that $\pi(K_{V_0}) \subset B(0, R_0)$. The barrier assumption means that there exists $\Sigma_{V_0} \subset p^{-1}(V_0)$ such that

$$p^{-1}(V_0) = K_{V_0} \cup \Sigma_{V_0}, \quad \Sigma_{V_0} \cap K_{V_0} = \emptyset, \quad \Sigma_{V_0} \text{ is closed.}$$  \hspace{1cm} (3.3)

The more general black box setting allows obstacle problems and other geometric situations. However, the barrier assumption cannot be satisfied for connected manifolds without having a nontrivial potential $V$.

We denote by $\text{Res}(P(h))$ the set of resonances of $P(h)$ (in an $h$-independent neighborhood of $\{\text{Re} \ z > 0, \text{Im} \ z > 0\}$).
Figure 3. Examples of one-dimensional potentials satisfying: (a) condition (1.2) and hence (3.3) and (4.1); (b) conditions (3.3) and (4.1), but not (1.2); (c) condition (3.3), but not (4.1); (d) neither (3.3) nor (4.1). The dashed line corresponds to $V_0$. In particular, examples (a) and (b) satisfy the assumptions of Theorems 2 and 3.

**Theorem 2.** Let $P(h)$ satisfy the general assumptions above. Suppose that $z_0 = z_0(h) \in \text{Res}(P(h))$, $\text{Re } z_0 = V_0 + \mathcal{O}(h)$, $z_0$ is simple, and

$$|\text{Im } z_0| = \mathcal{O}(h^\infty), \quad d(z_0(h), \text{Res}(P(h)) \setminus \{z_0(h)\}) > h^N, \quad (3.4)$$

for some $N$. Suppose that $\chi$ and $\psi$ are given by (1.3) with $R > R_0$. Then there exist $C_0 > 0$ and $h_0$ such that for $0 < h < h_0$,

$$\|\chi(P(h) - \text{Re } z_0 - i0)^{-1}\chi\|_{\mathcal{H} \to \mathcal{H}} \geq \frac{1}{C_0 |\text{Im } z_0|}, \quad (3.5)$$

and

$$\|\psi(P(h) - \text{Re } z_0 - i0)^{-1}\chi\|_{\mathcal{H} \to \mathcal{H}} \geq \frac{1}{C_0 \sqrt{|\text{Im } z_0|} h}. \quad (3.6)$$

**Remark.** As stated in the introduction, it is (3.6) that seems to be the novel aspect. The presence of the square root is (morally) consistent with the results of [3, Lemma A.2] and of [5, Theorem 2].

**Proof.** We only present the proof of (3.6). Using the involution $u \mapsto \bar{u}$ we define

$$(u \otimes v) f := u \langle f, \bar{v} \rangle,$$

where we use the inner product on the black box Hilbert space. Since $z_0$ is simple, we have

$$\psi(P(h) - z)^{-1}\chi = \frac{\psi u \otimes \chi u}{z - z_0} + \psi R_{z_0}(z, h) \chi,$$
where $u$ is the corresponding normalized resonant state and $R_{z_0}(z, h)$ is holomorphic in

$$[\Re z_0 - h^N, \Re z_0 + h^N] + i(-h^N, \infty).$$

From [15, (5.1)] and [1, (1.12)] (or [16, (8.18)]) we see that

$$\|\chi u\|_{\mathcal{H}_\ell} = 1 + \mathcal{O}(h^{\infty}), \quad u = \chi u + \mathcal{O}(h^{\infty})_{L^2_{\text{loc}}}. \quad (3.7)$$

Using the maximum principle as in [18, Lemma 2] and the estimates on the resolvent in [18, Lemma 1] we see that

$$\|\chi R_{z_0}(\Re z_0, h)\psi\|_{\mathcal{H}_\ell \rightarrow \mathcal{H}_\ell} = \mathcal{O}(h^{-M}), \quad (3.8)$$

for some $M$. Hence to obtain (3.6) we need to estimate

$$\frac{1}{|\Im z_0|} \|\psi u \otimes \chi u\|_{\mathcal{H}_\ell \rightarrow \mathcal{H}_\ell} = \frac{\|\psi u\|_{\mathcal{H}_\ell} \|\chi u\|_{\mathcal{H}_\ell}}{|\Im z_0|}, \quad (3.9)$$

from below.

To estimate $\|\psi u\|_{\mathcal{H}_\ell}$ from below we write

$$0 = \Im \langle (P(h) - z_0)u, 1_{B(0, R + t)} u \rangle_{\mathcal{H}_\ell}$$

$$= \Im \langle P(h)u, 1_{B(0, R + t)} u \rangle_{\mathcal{H}_\ell} - \Im z_0 \|1_{B(0, R + t)} u\|_{\mathcal{H}_\ell}^2.$$

Since $P(h)$ is self-adjoint on $\mathcal{H}$ and acts as a symmetric second order operator on $C_c^{\infty}(\mathbb{R}^n \setminus B(0, R_0))$, we obtain

$$\Im z_0 \|1_{B(0, R + t)} u\|_{\mathcal{H}_\ell}^2 = -h\Im \int_{\partial B(0, R + t)} \bar{u}N(x, hD)udS(x),$$

where $N(x, hD_x)$ is a first order semiclassical differential operator. For example, if $P(h) = -h^2 \Delta + V$, then $N(x, hD_x) = i(x/|x|) \cdot hD_x$.

Since from (3.7), $\|1_{B(0, R + t)} u\|_{\mathcal{H}_\ell}^2 = 1 + \mathcal{O}_1(h^{\infty})$, we see that

$$\frac{1}{3} |\Im z_0| \leq h \int_{\frac{1}{3}}^{\frac{2}{3}} \int_{\partial B(0, R + t)} |u| |N(x, hD_x)u| dS(x) dt$$

$$= h \int_{B(0, R + \frac{1}{3}) \setminus B(0, R + \frac{1}{4})} |u| |N(x, hD_x)u| dx$$

$$\leq C' h \int_{B(0, R + 1) \setminus B(0, R)} |u|^2 dx \leq C' h \|\psi u\|^2_{\mathcal{H}_\ell},$$

where we used the equation $(P - z_0)u = 0$ and elliptic estimates to control the first order term term $N(x, hD_x)u$. This shows that

$$\|\psi u\|_{\mathcal{H}_\ell} \geq \sqrt{|\Im z_0|/C'h},$$

which combined with (3.8), (3.9) and (3.7) completes the proof of (3.6).
4. A metric example

We start by using Theorem 2 to obtain a generalization of Theorem 1 to higher dimensions and to more general potentials:

**Theorem 3.** Consider a Schrödinger operator

\[ P(h) = -h^2 \Delta + V \]

on \( L^2(\mathbb{R}^n) \) where \( V \) satisfies (3.1) and (3.3). Suppose also that

\[ K_{V_0} = \{(x_0, 0)\}, \quad V'(x_0) = 0, \quad V''(x_0) > 0. \quad (4.1) \]

Then there exists \( z_0 \) satisfying the assumptions of Theorem 2 with

\[ d(z_0, \text{Res}(P(h)) \setminus \{z_0\}) > h/C, \quad |\text{Im} \ z_0| < e^{-c_0}/h. \quad (4.2) \]

In particular in the notation of (3.6),

\[ \|\psi(P(h) - \text{Re} \ z_0 \pm i0)^{-1} \chi\|_{L^2 \to L^2} \geq \exp \frac{c}{h}, \quad (4.3) \]

for \( 0 < h < h_0 \) and some \( c > 0 \).

**Proof.** The existence of \( z_0 \) follows from Corollary in [15, §5]. The reference operator \( P^\#(h) \) there can be chosen as \( P^\#(h) = -h^2 \Delta + V^\#(x) \), where \( V^\#(x) = V(x) \) in a small neighbourhood of \( x_0 \) where \( x_0 \) is the only critical point and \( V^\#(x) > V(x_0) + \varepsilon, \varepsilon > 0 \), outside of that neighbourhood. Since the eigenvalue of \( P^\#(h) \) corresponding to the minimum \( V_0 = V(x_0) \) is separated from other eigenvalues by \( h/C \) (see for instance [9] and references given there) the same corollary shows the separation from other resonances. \( \square \)

**Remarks.** 1. The condition (1.2) implies that (3.3) and (4.1) hold (since \( H_p(x \cdot \xi) > 0 \) on \( \{p = V_0\} \) except at \( x = \xi = 0 \)), but the converse is not true – see Figure 3.

2. When \( V \) is analytic and satisfies certain “well-in-the-island” hypotheses, Theorem 3 follows from the work of Helffer–Sjöstrand [10] and under these stronger assumptions Theorem 2 can then be proved in the same way using the earlier results of Gérard–Martinez [8] in place of the results of [15]. In particular, when \( n = 1 \) and \( V \) is even, by [10, (11.5)] we have

\[ \text{Im} \ z_0 = -C \ h^{1/2} e^{-S_0/h} (1 + \mathcal{O}(h)), \quad S_0 = \int_{\{x : V(x) > V_0\}} \sqrt{V(x)} dx. \]
Plugging this into (3.5) and (3.6) gives bounds with an explicit exponential rate:

$$\| \chi(P(h) - \text{Re} z_0 \pm i0)^{-1} \chi \|_{L^2 \to L^2} \geq \frac{1}{Ch^{1/4}e^{S_0/h}},$$

$$\| \psi(P(h) - \text{Re} z_0 \pm i0)^{-1} \chi \|_{L^2 \to L^2} \geq \frac{1}{Ch^{3/4}e^{S_0/2h}}.$$ 

See also [6, §2.8] for further explicit examples. It is natural to expect that such bounds also hold in the example from §2.

3. For $P(h) = -h^2 \Delta + V$, and for $E$’s satisfying (4.1) (with $V_0 = E$), a result of Nakamura [14, Proposition 4.1] and [15, Corollary, §5] show that

$$\| \chi(P(h) - E - i0)^{-1} \chi \|_{L^2 \to L^2} \leq C h^{-q}, \quad |E - z_j(h)| \geq h^q,$$

where $q \geq 1$ and $z_j(h)$ are the resonances of $P(h)$. Since the density of $\text{Re} z_j(h)$ satisfies a Weyl law, this means that the bound is $O(h^{-q})$, outside of a set of measure $O(h^{q-n})$, $q > n$.

The example in Theorem 3 can be used directly to obtain examples of resolvent growth for asymptotically conic metrics of the type studied by Rodnianski and Tao [17].

**Theorem 4.** Let $(M, g)$ be the following Riemannian manifold:

$$M = \mathbb{R}_x \times S^{n-1}_\theta, \quad g = dx^2 + V(x)^{-1} d\theta^2, \quad n > 1,$$

where $d\theta^2$ is the round metric on the sphere of radius 1 and $V(x) \in C^\infty(\mathbb{R}; (0, \infty))$ is a function satisfying the assumptions of Theorem 3 and

$$V(x) = \frac{1}{x^2}, \quad |x| \geq R_0.$$

Put

$$\chi(x) = 1_{|x| < R_0}, \quad \psi(x) = 1_{R_1 - 1 < |x| < R_1 + 1}, \quad R > R_0.$$

Then there exists a sequence $\lambda_k \to \infty$ such that

$$\| \psi(-\Delta_g - \lambda_k \pm i0)^{-1} \chi \|_{L^2(M) \to L^2(M)} \geq \exp(c \sqrt{\lambda_k}), \quad (4.4)$$

for some constant $c > 0$. 

Proof. In the \((x, \theta)\) coordinates, the Laplacian \(\Delta_g\) has the form

\[
\Delta_g = \partial_x^2 - \frac{(n - 1) V'(x)}{2V(x)} \partial_x + V(x) \Delta_S.
\]

Here \(\Delta_S\) is the Laplacian on \(S^{n-1}\). For \(k \geq 0\), let \(Y_k(\theta)\) be (any) spherical harmonic of order \(k\), i.e. a smooth function on \(S^{n-1}\) such that

\[
(-\Delta_S - k(k + n - 2)) Y_k = 0, \quad \|Y_k\|_{L^2(S^{n-1})} = 1,
\]

see for example [II, §17.2] for the spectrum of \(\Delta_S\). Then for \(u(x) \in C^\infty(\mathbb{R})\) and \(\lambda \in \mathbb{R}\), we have

\[
-\Delta_g(u(x)Y_k(\theta)) = \left( -\partial_x^2 + \frac{(n - 1) V'(x)}{2V(x)} \partial_x + k(k + n - 2)V(x) \right) u(x)Y_k(\theta).
\]

Put

\[
h_k := (k(k + n - 2))^{-1/2}
\]

so that

\[
h_k^2 (-\Delta_g - \lambda)(u(x)Y_k(\theta)) = (P(h_k) - h_k^2 \lambda) u(x)Y_k(\theta),
\]

where

\[
P(h) := -h^2 \partial_x^2 + \frac{(n - 1) V'(x)}{2V(x)} h^2 \partial_x + V(x).
\]

Let

\[
R(\lambda) := (-\Delta_g - \lambda)^{-1}
\]

for \(\lambda \not\in [0, +\infty)\). It follows that

\[
R(\lambda) = \sum_{k \in \mathbb{N}} h_k^2 (P(h_k) - h_k^2 \lambda)^{-1} \otimes \Pi_k : L^2(M) \longrightarrow L^2(M), \quad (4.5a)
\]

\[
L^2(M) \simeq L^2(\mathbb{R}, V(x)^{-\frac{n-1}{2}} dx) \otimes L^2(S^{n-1}), \quad (4.5b)
\]

where

\[
\Pi_k : L^2(S^{n-1}) \longrightarrow L^2(S^{n-1})
\]
is the orthogonal projection onto the space of spherical harmonics of order $k$. The operator
\[ R(\lambda) : C_c^\infty(M) \longrightarrow C^\infty(M) \]
continues meromorphically to $\text{Im} \lambda \leq 0$, and
\[ (P(h_k) - h_k^2 \lambda)^{-1} : C_c^\infty(\mathbb{R}) \longrightarrow C^\infty(\mathbb{R}) \]
continues meromorphically for each $k$. Hence (4.5) is valid for $\text{Im} \lambda \leq 0$, with the operator acting on
\[ C_c^\infty(M) \simeq C_c^\infty(\mathbb{R}) \otimes C_c^\infty(S^{n-1}). \]

Hence,
\[
\| \psi(-\Delta_g - \lambda \pm i0)^{-1} \chi \|_{L^2(M) \to L^2(M)} \\
= \| \psi R(\lambda \pm i0) \chi \|_{L^2(M) \to L^2(M)} \\
= \sup_{k \in \mathbb{N}} \| \psi (P(h_k) - h_k^2 \lambda \pm i0)^{-1} \chi \|_{L^2_{\lambda_k} \to L^2_{\lambda_k}},
\]
where
\[ L^2_{\lambda} := L^2(\mathbb{R}, V(x)^{-\frac{n-1}{2}} \, dx). \]

We now apply Theorem 3 to $P(h_k)$ and put
\[ \lambda_k = \text{Re} \, z_0(h_k) / h_k^2. \]

The estimate (4.4) follows from (4.3). Theorem 3 applies to the operator $P(h)$ despite the presence of a first order term, as this term is of order $O(h)$ in the semiclassical calculus and thus does not affect the classical Hamiltonian flow $H_p$, and the results of [15] and Theorem 2 apply to a wide class of semiclassical differential operators including $P(h)$.
